MEASURE *DHS+*

MEASURE *DHS+*

This report highlights the findings of the 2003 Ghana Demographic and Health Survey (GDHS), a nationally representative survey of 5,691 women age 15-49 and 5,015 men age 15-59. The primary purpose of the GDHS is to generate recent and reliable information on fertility, family planning, infant and child mortality, maternal and child health, and nutrition. In addition, the survey collected information on malaria treatment and prevention, anaemia and HIV prevalence. This information is essential for making informed policy decisions, planning, monitoring, and evaluating programmes on health in general and reproductive health in particular, at both the national and regional levels. This survey is the fourth in a series of population and health surveys conducted in Ghana as part of the global Demographic and Health Surveys (DHS) programme.

The 2003 GDHS was implemented by the Ghana Statistical Service (GSS) in collaboration with the Noguchi Memorial Institute for Medical Research (NMIMR) and the Ghana Health Service. Technical assistance was provided by ORC Macro through the MEASURE DHS programme. Financial support for the survey was provided by the U.S. Agency for International Development (USAID) and the Government of Ghana.

Additional information about the GDHS may be obtained from the Ghana Statistical Service, P.O. Box 1098, Accra, Ghana (Telephone: (233-21) 671-732 and Fax: (233-21) 671-731). Information about the DHS project may be obtained from ORC Macro, 11785 Beltsville Drive, Calverton, MD (Telephone: 301-572-0200; Fax: 301-572-0999; E-mail: reports@orcmacro.com; Internet: http://www.measuredhs.com).

FOREWORD

The 2003 Ghana Demographic and Health Survey (GDHS) is a nationwide sample survey carried out to provide information on population, family planning, maternal and child health, nutrition, childhood mortality, and AIDS and sexually transmitted infections (STIs). This is the fourth survey of its kind to be undertaken in Ghana, others being in 1988, 1993, and 1998. This latest GDHS included, for the first time, testing of blood samples to provide national rates of anaemia and HIV. All four demographic and health surveys have been implemented by the Ghana Statistical Service, in close collaboration with other stakeholders.

The Statistical Service of Ghana acknowledges the invaluable assistance given by a number of organisations and individuals both local and international towards the successful implementation of the 2003 GDHS.

The Service is grateful to the Ministry of Health and the Ghana Health Service for releasing nurses for the survey fieldwork and personnel for training the interviewers. Our appreciation also goes to the Ghana AIDS Commission for their support at the time of training and in helping to set up VCT centres as a follow-on to the HIV testing in the survey.

We sincerely thank the Ghana Registered Midwives Association (GRMA) and the National Population Council (NPC) for providing vehicles for the data collection.

We are very grateful to all members of the National Steering Committee, the Ethics Committee and the project personnel for their immense support and contribution during the different phases of the survey.

We appreciate the work done by the Noguchi Memorial Institute for Medical Research on HIV testing, and especially commend the laboratory team assigned to work on the blood samples for their tireless efforts in getting the testing done successfully.

The Service is particularly thankful to the United States Agency for International Development (USAID) for funding the survey through its mission in Ghana, and to ORC Macro for providing technical assistance.

We thank the authors of this report. They are mentioned specifically by name at the beginning of this report.

We owe an immense gratitude to the field coordinators, interviewers, nurses, laboratory personnel, supervisors, field editors, regional statisticians, and drivers for their hard work and dedication. We have printed the names of all survey personnel in Appendix D as a sign of our appreciation for their valuable assistance.

Most of all, we truly appreciate the co-operation of all survey respondents in making the 2003 GDHS a success.

Dr. Grace Bediako,
Government Statistician,
Ghana Statistical Service

CONTRIBUTORS

This report was authored by the following persons:

Dr. Clement Ahiadeke, Institute for Social, Statistical and Economic Research
Mrs. Faustina Ainguah, Ghana Statistical Service
Dr. William Ampofo, Noguchi Memorial Institute for Medical Research
Mr. Jacob Arthur-Quarm, Noguchi Memorial Institute for Medical Research
Dr. Amanua Chinbuah, Ghana Health Service, Health Research Unit
Dr. Agnes Dzokoto, National AIDS Control Programme
Dr. Pav Govindasamy, ORC Macro
Mr. Steve Grey, National Population Council
Dr. Steven O. Kwankye, Regional Institute for Population Studies
Mr. Emmanual Larbi, Ghana AIDS Commission
Mrs. Edith Mote, Ghana Statistical Service
Dr. Gloria Quansah-Asare, Ghana Health Service, Maternal and Child Health/Family Planning Unit
Dr. Isabella Sagoe-Moses, Ghana Health Service, Nutrition Unit
Mrs. Jasbir Sangha, ORC Macro
Dr. Tesfay Teklu, Regional Institute for Population Studies

SUMMARY OF FINDINGS

The 2003 Ghana Demographic and Health Survey (2003 GDHS) is a nationally representative survey of 5,691 women age 15-49 and 5,015 men age 15-59 from 6,251 households covering 412 sample points (clusters) throughout Ghana. This survey is the fourth in a series of national-level population and health survey conducted as part of the global Demographic and Health Surveys (DHS) program and is designed to provide data to monitor the population and health situation in Ghana as a follow-up of the 1988, 1993 and 1998 GDHS surveys. The survey utilised a two-stage sample based on the 2000 Population and Housing Census and was designed to produce separate estimates for key indicators for each of the ten regions in Ghana. Data collection took place over a three-month period, from late July to late October 2003.

The survey obtained detailed information on fertility levels, marriage, sexual activity, fertility preferences, awareness and use of family planning methods, breastfeeding practices, nutritional status of women and young children, childhood mortality, maternal and child health, awareness and behaviour regarding HIV/AIDS, and other sexually transmitted infections (STIs). In addition, the 2003 GDHS collected information on malaria and use of mosquito nets, and carried out anaemia testing in children and women and HIV testing in adults.

The 2003 GDHS was implemented by the Ghana Statistical Service (GSS) in collaboration with the Noguchi Memorial Institute for Medical Research (NMIMR) and the Ghana Health Service. Technical assistance was provided by ORC Macro through the MEASURE DHS programme. Financial support for the survey was provided by the U.S. Agency for International Development (USAID) and the Government of Ghana.

FERTILITY

Fertility Levels and Trends. Comparison of the data from the 2003 GDHS with the three earlier DHS surveys indicates that the dramatic decline in fertility experienced in the eighties and nineties appears to have slowed down. The TFR, estimated for the three years preceding each survey, declined dramatically from 6.4 children per woman in 1988 to 5.2 children per woman in 1993, and to 4.4 children in 1998, a nearly 2-child drop in fertility over the decade. However, the demographic transition experienced in Ghana seems to have stalled in the last three years even though contraceptive use has continued to rise. Nevertheless, with a current TFR of 4.4, Ghana's fertility rate is one of the lowest in sub-Saharan Africa.

Fertility Differentials. Differentials by background characteristics are marked. Rural women have nearly twice as many children (5.6 children per woman) as urban women (3.1 children per woman). The total fertility rate is highest in the Northern Region (7.0 children per woman) and lowest in Greater Accra (2.9 children per woman). As expected, women's education is strongly associated with lower fertility, decreasing from 6.0 children per woman among those with no education to 2.5 children per woman among those with at least secondary education. Similar differentials are observed by wealth quintile, with TFR decreasing from 6.4 children per woman among women in the lowest wealth quintile to 2.8 children per woman among those in the highest wealth quintile.

Unplanned Fertility. Despite a steady rise in the level of contraceptive use over the last fifteen years, the 2003 GDHS data indicate that unplanned pregnancies are common in Ghana. Overall, 16 percent of births in Ghana are unwanted, while 24 percent are mistimed (wanted later). The proportion of unplanned births declined slightly from 42 percent in 1993 to 36 percent in 1998 but rose again to 40 percent in 2003. What is more troubling, however, is the fact that the proportion of births that are unwanted has increased rather dramatically from the 1993 level of 9 percent to 16 percent in 2003.

Fertility Preferences. There is considerable desire among currently married Ghanaians to control the timing and number of births. Thirty-eight percent of currently married women would like to wait for two years or more for the next birth, and 36 percent do not want to have another child. About a fifth (18 percent) would like to have a child soon (within two years). A comparison of the data over the four DHS surveys show that the desire to space births among currently married women has declined in the last 15 years, from 45 percent in 1988 to 38 percent in 2003. On the other hand, the desire to limit has increased from 23 percent in 1988 to 34 percent in 2003. However, this change has been minimal in the last ten years.

There has been a decline in ideal family size among currently married women over time, from a mean of 5.5 children in 1988 to 4.8 children in 2003. There has been little change in the ideal number of children over the last 10 years.

FAMILY PLANNING

Knowledge of Contraception. Knowledge of family planning is nearly universal, with 98 percent of all women age 15 to 49 and 99 percent of all men age 15 to 59 knowing at least one modern method of family planning. Among all women, the most widely known methods of family planning are the male condom (95 percent), injectables (89 percent), the pill (88 percent) and female condom (83 percent). Seventy percent of all women have heard of female sterilisation, while 61-65 percent have heard of the IUD, implants, and periodic abstinence.

There has been an increase in levels of awareness of contraceptive methods over time. Among all women, the proportions who know any method has risen since 1988 for all methods (from 76 percent in 1988, 91 percent in 1993, 93 percent in 1998 and 98 percent in 2003). The proportions who know of implants has risen steeply since 1993 (from 4 percent in 1993, 21 percent in 1998 and 62 percent in 2003). A similar trend is seen among men with remarkable increases in knowledge of IUD, male sterilisation and LAM.

Use of Contraception. The contraceptive prevalence rate among married women is 25 percent. The most commonly used modern method among married women is the pill (6 percent), followed closely by injectables (5 percent). Male condoms and female sterilisation are used by 3 percent and 2 percent of married women, respectively, while implants and IUD are used by 1 percent each. The most commonly used traditional method is periodic abstinence, used by 5 percent of married women.

Trends in Contraceptive Use. Current use of contraception by married women has increased from 13 percent in 1988, 20 percent in 1993, 22 percent in 1998 and 25 percent in 2003. There has been a steady increase in the use of modern methods from 5 percent in 1988 to 19 percent in 2003. However, while there was an increase in the use of traditional methods from 8 percent in 1988 to 10 percent in 1993, use of these methods have since decreased to 9 percent in 1998 and to 7 percent in 2003. Use of male condoms, pills, injectables and implants has increased.

Differentials in Contraceptive Use. Women in urban areas are more likely to use contraceptive methods (31 percent) than their rural counterparts (21 percent). Male condoms, IUD, and female sterilisation use in urban areas is two to three times higher than in rural Ghana. The more urbanised regions such as Greater Accra and Brong-Ahafo have contraceptive prevalence rates above 30 percent. Two of the three northern regions (Upper East and Northern) report low levels of contraceptive use (12 percent each). Women with at least some secondary education are more than twice as likely to use contraception as women with no education. The proportion currently using contraception generally increases with increasing number of children. Fourteen percent of women without children are currently using contraceptive methods, compared with 26 percent of women with five or more children. Wealth and current use of contraception is positively related, increasing from 14 percent among currently married women in the lowest quintile to 35 percent in the highest quintile.

Source of Modern Methods. In Ghana, both the public and private sectors are important sources of supply for users of modern methods (41 percent and 54 percent, respectively). The most common public sector source are government hospitals and polyclinics, which provide most of the services (26 percent), while government health centres and family planning clinics provide 11 percent and 4 percent of users, respectively.

In the last five years, there has been a shift in the source of modern contraceptive methods from the public to the private sector. The proportion of current users relying on private medical sources has increased from 45 percent in 1998 to 54 percent in 2003, while the reliance on public sources for all modern methods decreased from 47 percent in 1998 to 41 percent in 2003.

Unmet Need for Family Planning. Thirty-four percent of married women have an unmet need for family planning. Unmet need for spacing is higher than unmet need for limiting children (22 percent and 12 percent, respectively), unchanged since 1998. Only 43 percent of the demand for family planning is currently being met, implying that the needs of more than one in two Ghanaian women are currently not being met.

MATERNAL HEALTH

Antenatal Care. A relatively high percentage of women received antenatal care from a trained health professional (21 percent from a doctor and 71 percent from a nurse/midwife). One percent of mothers received antenatal care from a traditional birth attendant (TBA) and 6 percent received no antenatal care. A comparison of the 2003 GDHS data with data from the three earlier DHS surveys show that there has been an improvement in the utilization of antenatal services in the last fifteen years from 82 percent of mothers receiving care for their most recent birth in the five-year period preceding the survey in 1988, to 92 percent in 2003.

Half of women received at least two doses of tetanus toxoid for their most recent birth in the five years preceding the survey, a third of

women received only one tetanus toxoid injection and 14 percent received none. The data show that there has been an improvement in tetanus toxoid coverage, for the most recent birth in the five years preceding the survey, over the last fifteen years, from 70 percent in 1988 to 83 percent in 2003.

With regard to anti-malarial indicators, the data show that 10 percent of pregnant women slept under a net, 4 percent slept under an ever-treated net, and 3 percent slept under an insecticide treated net (ITN), the night before the interview with no difference in the use of nets between pregnant and non-pregnant women. The data show that 58 percent of mothers reported that they received anti-malarial drugs for the prevention of malaria during pregnancy. It also shows that chloroquine is more frequently (12 percent) taken than SP/Fansidar (1 percent), presumably because the old programme was still in force during the fielding of the survey. The 1 percent of women who used SP/Fansidar received the drug during an antenatal visit.

Delivery Care. Nationally, 46 percent of births in the last five years are delivered in health facilities, with 36 percent in public health facilities and 9 percent in private health facilities. About half of births (53 percent) occur at home. The data also show that medically trained providers assisted with 47 percent of deliveries, TBAs assisted with 31 percent of deliveries and relatives or friends attended 19 percent of deliveries. Medically assisted deliveries continue to be low in Ghana, with less than fifty percent benefiting from professional delivery assistance over the last fifteen years.

Postnatal Care. One in four women who had a non-institutional live birth in the five years preceding the survey received postnatal care within two days of delivery, one in ten women received postnatal care 3-6 days after delivery and one in eight received postnatal care 7-41 days after delivery. More than half of women who had a non-institutional birth in the five years preceding the survey did not receive postnatal care at all.

CHILD HEALTH

Childhood Mortality. Data from the 2003 GDHS show that there has been a slowing down in the mortality decline over the last five years. Data for the most recent five-year period suggests that one in every nine Ghanaian children dies before reaching age five. Nearly three in five of these deaths occur in the first year of life—infant mortality is 64 deaths per 1,000 live births and child mortality is 50 deaths per 1,000 children age one. Neonatal mortality is 43 deaths per 1,000 live births in the most recent five-year period, while postneonatal mortality is 21 deaths per 1,000 live births. Neonatal deaths account for two-thirds of the deaths in infancy.

Childhood Vaccination Coverage. Sixty-nine percent of Ghanaian children age 12-23 months are fully immunised, while 5 percent received no vaccinations at all. Nine in ten children have received the BCG and first dose of DPT and polio vaccines. While the coverage for the first dose of DPT and polio is high, coverage declines for subsequent doses of DPT and polio, with only about 80 percent of children receiving the recommended three doses of these vaccines. Eighty-three percent of children received the measles vaccine and 77 percent have been vaccinated against yellow fever. The percentage of children age 12-23 months who have been fully vaccinated has increased over the last twenty years, from 47 percent in 1988 to 69 percent in 2003.

Child Illness and Treatment. Among children under five years of age, 10 percent were reported to have had symptoms of acute respiratory illness in the two weeks preceding the survey. Of these, 44 percent were taken to a health facility or provider for treatment. Fifteen percent of children under five years had diarrhoea in the two weeks preceding the survey. Twenty-six percent of children with diarrhoea were taken to a health provider. Just over a third of children with diarrhoea (39 percent) were given a solution made from oral rehydration salts (ORS), 11 percent received recommended home fluids (RHF) and 40 percent were given increased fluids. Overall, 63 percent received ORS, RHF, or increased fluids.

Twenty-one percent of children under five years had a fever in the two weeks preceding the survey. Of these, 63 percent took an anti-malarial drug. Forty-four percent of children took the anti-malarial drug on the same day or the next after the onset of the illness. Chloroquine is by far the most common anti-malarial drug taken for fever (59 percent), followed by Amodiaquine and Quinine (2 percent each) and SP/Fansidar (less than 1 percent).

NUTRITION

Breastfeeding Practices. The data indicate that almost all (97 percent) Ghanaian children are breastfed for some period of time. Forty-six percent of infants were put to the breast within one hour of birth, and 75 percent started breastfeeding within the first day. The data from 2003 can be compared with similar data collected five years ago. The data show that over the last five years, there was little difference in the percent of children ever breastfed.

The 2003 GDHS data indicate that supplementary feeding of children begins early. For example, among newborns less than two months of age, 38 percent are receiving supplementary foods or liquids other than water. The median duration of breastfeeding in Ghana is 23 months.

Twelve percent of children under six months are given a feeding bottle with a nipple. Bottle-feeding reaches its peak (15 percent) at age 4-5 months. The percentage of young children bottle-fed has declined markedly over the last five years.

Iodisation of household salt. Ninety percent of the households interviewed in the 2003 GDHS had their salt tested for iodine, while 9 percent had no salt available in the household. Fifty-nine percent of households are consuming salt that is not iodised, 13 percent of households are consuming inadequately iodised salt (<15 ppm) and only 28 percent are consuming adequately iodised salt (15+ ppm).

Intake of Vitamin A. Ensuring that children between six months and 59 months receive enough vitamin A may be the single most effec-

tive child survival intervention, since deficiencies in this micronutrient can cause blindness and can increase the severity of infections, such as measles and diarrhoea. Seventy-eight percent of children 6-59 months are reported to have received a vitamin A supplement in the 6 months preceding the survey. Forty-one percent of children under three who live with their mothers consume fruits and vegetables rich in vitamin A.

Forty-three percent of mothers with a birth in the last five years reported receiving a vitamin A dose postpartum. Eight percent of interviewed women reported night blindness during pregnancy. When adjusted for blindness not attributed to vitamin A deficiency during pregnancy, the data show only two percent of women reported night blindness during their last pregnancy.

Prevalence of anaemia. Iron-deficiency anaemia is a major threat to maternal health and child health. Overall, more than three-quarters of Ghanaian children 6-59 months old have some level of anaemia, including 23 percent of children who are mildly anaemic, 47 percent who are moderately anaemic and 6 percent who are severely anaemic.

The prevalence of anaemia is less pronounced among women than among children. Forty-five percent of Ghanaian women age 15-49 are anaemic, with 35 percent mildly anaemic, 9 percent moderately anaemic, and less than 1 percent severely anaemic.

Nutritional Status of Children. According to the 2003 GDHS, 30 percent of children under five are stunted and 11 percent severely stunted. Seven percent of children under five are wasted and 1 percent severely wasted. Weight-for-age results show that 22 percent of children under five are underweight, with 5 percent severely underweight. Children whose biological mothers were not in the household are more likely to be malnourished (34 percent stunted, and 25 percent underweight) than children whose mothers were interviewed.

The proportion of children under five who are stunted has increased from 26 percent in 1998 to 30 percent in 2003. The proportion underweight decreased from 10 percent in 1998 to 7 percent in 2003. The proportion of children who are wasted also decreased from 25 percent in 1998 to 22 percent in 2003.

Nutritional Status of Women. The mean height of Ghanaian women is 159 centimetres, which is above the critical height of 145 centimetres. Only 1 percent are below 145 centimetres. Nine percent of women were found to be chronically malnourished (BMI less than 18.5), while 25 percent are overweight or obese. There has been little change in the percentage of mothers whose height is below 145 centimetres and in the mean BMI over the last ten years from 1993 to 2003.

HIV/AIDS

Awareness of AIDS. Almost all (98 percent) women and men (99 percent) have heard of AIDS indicating that awareness of AIDS in Ghana is universal. Thirty-seven percent of women and 38 percent of men age 15-49, know someone personally who has the virus that causes AIDS or who has died of AIDS. Seventy-three percent of women and 82 percent of men know that condom use is a major prevention method. Eighty-six percent and 90 percent of women and men, respectively, know that limiting sex to only one uninfected partner is vital to the prevention of HIV. Sixty-nine percent of women and 78 percent of men know that these two preventive measures in combination can reduce the risk of HIV infection. In addition, 79 percent of women and 83 percent of men know that abstinence can prevent HIV infection.

About four in five women and men correctly know that a healthy looking person can have the AIDS virus. Fifty-five percent of women and sixty percent of men know that AIDS cannot be transmitted through mosquito bites. Less than half of women and three-fifths of men know that AIDS cannot be transmitted by supernatural means. More than 70 percent of women and men know that a person cannot be-

come infected with HIV/AIDS by sharing food with someone who has AIDS.

General knowledge on HIV transmission during pregnancy, delivery and breastfeeding is relatively high and ranges between 69 and 75 percent among women and 74 to 82 percent among men. However, few women and men (16 percent each) know that the risk of MTCT can be reduced if a mother takes special drugs during her pregnancy.

Attitudes Towards People Living with HIV/AIDS. It is encouraging to see that more than two-thirds of women and men age 15-49 are willing to care for a family member with HIV in their own household, and that three-fifths of women and two-thirds of men do not believe that the HIV positive status of a family member should be kept a secret. Two-fifths of women and half of men also believe that an HIV positive female teacher should be allowed to continue teaching. However, only one in four women and one in three men say that they would buy fresh vegetables from a vendor with AIDS.

HIV-Related Behavioural Indicators. One of the strategies for reducing the risk of contracting an STI is for young persons to delay the age at which they become sexually active. Seven percent of women and 4 percent of men had sex by exact age 15. Forty-six percent of women and 27 percent of men first had sex by exact age 18.

Sexual intercourse with a non-marital or non-cohabiting partner is associated with an increased risk of contracting sexually transmitted diseases. One in five women and two in five men age 15-49 reported engaging in higher-risk sexual behaviour. Even more disturbing is the fact that half of women age 15-24 and more than four-fifths of men in the same age cohort engage in risky sexual behaviour.

Sexual intercourse with more than one partner is also associated with a high risk of exposure to sexually transmitted diseases. One percent of women and 10 percent of men age 15-49 report having had sexual intercourse with more than one partner in the twelve months prior to the survey.

Promoting the use of condoms is an important strategy in the fight against HIV/AIDS transmission. Overall, only 28 percent of women and 45 percent of men age 15-49 used a condom during their last episode of higher-risk sex.

HIV Prevalence. HIV tests were conducted for 89 percent of the 5,949 eligible women and 80 percent of the 5,345 eligible men. Results from the 2003 GDHS indicate that 2 percent of Ghanaian adults are HIV positive. HIV prevalence in women age 15-49 is nearly 3 percent, while for men 15-59, it is under 2 percent. This female-to-male ratio of 1.8 to 1 is higher than that found in most population-based studies in Africa and implies that young women are particularly vulnerable to HIV infection compared with young men. Prevalence among females is consistently higher than among males at all age groups except at ages 40-44, where male prevalence is higher. The female-male gap is particularly large among women and men age 25-29, where women are nearly three and a half times as likely to be HIV positive as men. The peak prevalence among women is at age 35-39 (5 percent), while prevalence rises gradually with age among men to peak at age 40-44 (4 percent).

Patterns of HIV Prevalence. Urban residents have only a slightly higher risk of being HIV positive than rural residents with the urban-rural difference among women slightly higher than among men. Overall prevalence is highest in the Eastern Region (4 percent), followed by the Western and Brong Ahafo regions (3 percent each). Prevalence is lowest in the Northern, Central and Volta regions (1 percent each). Gender differences are apparent in all the regions. Those who have completed primary and middle/JSS education are more likely to be HIV positive than those with either no education or at least secondary education. Work status is related to HIV prevalence among both women and men, with prevalence twice as high among those currently working than those not currently working. Prevalence is highest among both women and men in the middle wealth quintile.

Prevalence is significantly higher among widowed women (7 percent), followed closely by divorced or separated women (6 percent). Among men, prevalence is markedly higher among divorced or separated men (6 percent).

Results from the 2003 GDHS indicate that, for the vast majority (96 percent) of cohabiting couples, both partners are HIV negative, while only in 1 percent of couples, are both partners HIV positive. There is discordance in the HIV positive status in under 2 percent of couples, where one partner is infected and the other is not.

GHANA

INTRODUCTION

<div style="text-align: right; font-size: 2em;">1</div>

1.1 GEOGRAPHY, HISTORY, AND ECONOMY

1.1.1 Geography

The Republic of Ghana is centrally located in West Africa and has a total land area of 238,537 square kilometres. It is bordered by French-speaking countries, on the east by the Republic of Togo, on the north and northwest by Burkina Faso, and on the west by Côte d'Ivoire. The Gulf of Guinea lies to the south and stretches across the 560 kilometres of the country's coastline.

Ghana is a lowland country, except for a range of hills that lie on the eastern border and Mt. Afadjato, the highest point of about 884 metres above sea level, which is to the west of the Volta River. Ghana can be divided into three distinguishable ecological zones: the sandy coastline backed by a coastal plain that is crossed by several rivers and streams; the middle belt and western parts of the country, heavily forested with many streams and rivers; and an undulating savannah to the north that is drained mainly by the Black and White Volta Rivers. The Volta Lake, created as a result of a hydroelectric dam in the east, is one of the largest artificial lakes in the world.

The climate of Ghana is tropical, but temperatures and rainfall vary by distance from the coast and elevation. The average annual temperature is about 26ºC (79º F). There are two distinct rainy seasons, April to June and September to November. In the north, however, the rainy season begins in March and lasts until September. Annual rainfall ranges from about 1,015 millimetres (40 inches) in the north to about 2,030 millimetres (80 inches) in the southwest. The *harmattan*, a dry desert wind, blows from the northeast between December and March, lowering the humidity and creating very warm days and cool nights in the north. In the south, the effects of the harmattan are felt mainly in January.

1.1.2 History

Ghana gained its independence from British rule on 6 March 1957, and on 1 July 1960 became a sovereign state in the British Commonwealth of Nations. The administrative and political capital of the country is Accra, with a population of 1.7 million (GSS, 2002). Ghana is a constitutional democracy and currently operates a multi-party democratic presidential system of government following the promulgation of the 1992 fourth Republic Constitution of Ghana. The country has an Executive Presidency elected for four years with a maximum of two terms. There is a parliament elected every four years, an independent judiciary, and a vibrant media.

The population is made up of several ethnic groups. The Akans constitute the largest ethnic group (49 percent) followed by the Mole-Dagbon (17 percent), Ewe (13 percent), and Ga/Dangme (8 percent). Various smaller ethnic groups can also be found in many parts of the country (GSS, 2002).

Ghana is divided into 10 administrative regions, Western, Central, Greater Accra, Volta, Eastern, Ashanti, Brong Ahafo, Northern, Upper East, and Upper West. The regions are further divided into 138 districts to ensure efficient and effective administration at the local levels.

1.1.3   Economy

The structure of the economy has not changed much over the past two decades. Agriculture, mining, logging, and retail trade are still the most important areas of economic activity. Agriculture is the main sector and employs about 50 percent of the population (GSS, 2002). High proportions of the working population in Ghana are concentrated in the informal sector, made up largely of self-employed persons.

The leading exports of the country are cocoa, gold, and timber. In recent times, the economy has diversified and includes exports of non-traditional commodities such as pineapples, bananas, yams, and cashew nuts. Tourism is fast gaining prominence as a foreign exchange earner.

The overriding objective of the Government of Ghana's (GoG) economic development programme is poverty reduction and general improvement in the welfare of all Ghanaians. In 1995, the GoG developed the Vision 2020 strategy for poverty reduction, which emphasises economic growth, integrated rural development, expansion of employment opportunities, and improved access, especially by the rural and urban poor, to basic public services such as education, health care, water and sanitation, and family planning services (World Bank, 2003). Under this strategy, it is envisaged that national income will grow by at least 8 percent from the current 4-5 percent.

1.2   DEMOGRAPHIC PROFILE

Ghana has undertaken four censuses since independence in 1957. The first was conducted in 1960, recording a population of 6.7 million. The 1970 Census reported Ghana's population as 8.6 million with an intercensal growth rate of 2.4 percent. The 1984 and 2000 censuses put the population at 12.3 million and 18.9 million, respectively, with an average growth rate of 2.7 percent between the two census periods (Table 1.1). The population density per square kilometre has more than doubled from 36 persons in 1970 to 79 persons in 2000. The proportion urban increased significantly from 29 percent in 1970 to 44 percent in 2000.

Table 1.1 Basic demographic indicators

Selected demographic indicators for Ghana, 1970, 1984, 2000

Indicator	1970	1984	2000
Population (millions)	8.6	12.3	18.9
Intercensal growth rate (percent)	2.4	2.6	2.7
Density (pop./km^2)	36.0	52.0	79.3
Percent urban	28.9	32.0	43.8
Sex ratio	98.5	97.3	97.9
Proportion age 0-14 years	46.9	45.0	41.3
Proportion age 65+	3.6	4.0	5.3
Life expectancy (years)			
Male	u	50.3	55.4
Female	u	53.8	59.6

u=Unknown (Not available)
Source: GSO, 1979; GSS, 1985; GSS, 2002

The sex ratio over the last 30 years has fallen slightly from 98.5 males per 100 females in 1970 to 97.9 in 2000. The proportion of the population under 15 years however, has decreased from 47 percent in 1970 to 41 percent in 2000, while the proportion 65 years and older increased from less than 4 percent to a little more than 5 percent over the same period. The changes observed in the age structure may be attributed to

declining fertility and improvements in the health conditions of the people. Life expectancy at birth has increased from 50 years among males in 1984 to 55 years in 2000 and among females from 54 years to 60 years over the same period.

1.3   POPULATION POLICY AND REPRODUCTIVE HEALTH PROGRAMMES

Ghana's population policy was formulated and adopted in 1969 in recognition of the high population growth and fertility rates observed at the time. After 25 years of implementation, however, the 1969 population policy made only a modest impact. It was therefore revised in 1994 to take into account emerging issues such as HIV/AIDS, population and the environment, concerns about the elderly and children, and also to develop new strategies that would ensure the achievement of the revised policy objectives. This meant ensuring the systematic integration of population issues in all areas of development planning.

Major targets aimed at achieving these objectives include the following: the reduction of the total fertility rate from 5.5 in 1993 to 5.0 by the year 2000; the achievement of a contraceptive prevalence rate of 15 percent for modern methods by the year 2000, and 50 percent by the year 2020; and the reduction in the annual population growth rate from about 3 percent per annum to 2 percent by the year 2020 (World Bank, 2003). The attainment of these policy goals is recognised as integral components of the national strategy to accelerate the pace of economic development, eradicate poverty, and enhance the quality of life of all citizens as outlined in the Vision 2020 Plan of Action. It is expected that these goals would propel Ghana into middle-income country status by the year 2020.

The National Population Council and its Secretariat were established in 1992 as the highest statutory body to advise the government on population related issues as well as to facilitate, monitor, coordinate, and evaluate the implementation of population programmes of other organisations both public and private within the country.

Ghana, in collaboration with the United Nations Fund for Population Activities (UNFPA), the United States Agency for International Development (USAID), the World Bank, and other development partners, has implemented several projects aimed at reducing reproductive health problems among the population. The support from these agencies is geared towards strategies on policy coordination and implementation as well as service delivery.

The government is committed to improving access and equity of access to essential health care, and ensuring that the health sector plays a key role in the Ghana Poverty Reduction Strategy (GPRS). The priority health intervention areas identified include addressing the problems of HIV/AIDS and other sexually transmitted infections (STIs), malaria, tuberculosis, guinea worm disease, poliomyelitis, reproductive health, maternal and child health, accidents and emergencies, non-communicable diseases, oral health and eye care, and specialised services.

The spread of HIV/AIDS is currently receiving considerable attention from the government and its development partners, with the immediate challenges including ensuring implementation of the Ghana HIV/AIDS Strategic Framework: 2001-2005 (World Bank, 2003). The objectives of the framework include reducing new HIV infections among the 15-49 age group and other vulnerable groups, and especially among the youth by the year 2005, improving service delivery and mitigating the impact of HIV/AIDS on individuals, the family, and the community by the year 2005, reducing individual and societal vulnerability and susceptibility to HIV/AIDS through the creation of an enabling environment for the implementation of the national response, and establishing a well managed multi-sectoral and multi-disciplinary institutional framework for the coordination and implementation of HIV/AIDS programmes in the country.

The government recognises that a critical constraint to poverty reduction is the limited choice of contraceptives especially to poor families. A two-pronged strategy will be employed to address this issue. The first is to decentralise service delivery and expand the sale of contraceptives through community agents, including maternity homes and field workers. The second, a national campaign on fertility regulation, will be instituted and will include a comprehensive, systematic, and culturally sensitive information, education, and communication programme to promote the use of family planning (World Bank, 2003).

In addition, the GPRS emphasises cost-effective interventions on immunisations and supervised delivery; a high impact and rapid delivery programme to reduce under-five and maternal mortality and malnutrition, especially in the three northern and central regions of the country; prevention and effective treatment of malaria and the availability and use of insecticide-treated bed nets; and the eradication of guinea worm (World Bank, 2003).

1.4   OBJECTIVES AND ORGANISATION OF THE SURVEY

The principal objective of the 2003 Ghana Demographic and Health Survey (GDHS) is to provide data to monitor the population and health situation in the country. This is the fourth round in a series of national-level population and health surveys conducted in Ghana under the worldwide Demographic and Health Surveys Program. The primary objective is to provide current and reliable data on fertility and family planning behaviour, infant and child mortality, breastfeeding, antenatal care, children's immunisations and childhood diseases, nutritional status of mothers and children, use of maternal and child health services, and awareness and behaviour regarding AIDS and other STIs. New features of the 2003 GDHS include the collection of information on female and male circumcision, information on malaria and ownership and use of insecticide-treated bed nets, and haemoglobin and HIV testing.

The long-term objective of the survey includes strengthening the technical capacity of major government institutions, including the Ghana Statistical Service (GSS). The 2003 GDHS also provides comparable data for long-term trend analyses in Ghana, since the surveys were implemented by the same organisation, using similar data collection procedures. It also contributes to the ever-growing international database on demographic and health-related information.

The 2003 GDHS was conducted by the Ghana Statistical Service in collaboration with the Noguchi Memorial Institute for Medical Research (NMIMR) and the Ghana Health Service. ORC Macro provided technical support for the survey through the MEASURE *DHS+* programme. Funding for the survey came from the U.S. Agency for International Development (USAID), through its office in Ghana, and the Government of Ghana.

1.5   SAMPLE DESIGN

The sample for the 2003 GDHS covered the population residing in private households in the country. A representative probability sample of about 6,600 households was selected nationwide. The list of enumeration areas (EAs) from the 2000 Ghana Population and Housing Census was used as a frame for the sample. The frame was first stratified into the 10 administrative regions in the country, then into rural and urban EAs. The sample was selected in such a manner as to allow for separate estimates for key indicators for the country as a whole, for each of the 10 regions in Ghana, as well as for urban and rural areas separately.

The 2003 GDHS used a two-stage stratified sample design. At the first stage of sampling, 412 sample points or EAs were selected, each with probability proportional to size, based on the number of households. A complete household listing exercise was carried out between May and June 2003 within all the selected EAs (clusters). The second stage of selection involved systematic sampling of households from this list. The sample selected per EA varied by region depending on the population size. Fifteen households per EA were

selected in all the regions except in Brong Ahafo, Upper East, and Upper West regions, where 20 households per EA were selected, and in the Northern region, where 16 households per EA were selected. The objective of this exercise was to ensure adequate numbers of complete interviews to provide estimates for important population characteristics with acceptable statistical precision. Due to the disproportional number of EAs and different sample sizes selected per EA among regions, the household sample for the 2003 GDHS is not self-weighted at the national level. The sample design is discussed in detail in Appendix A, and the methodology used in estimating sampling errors together with a list of sampling errors for key variables are provided in Appendix B.

1.6   QUESTIONNAIRES

All women age 15-49 and all men age 15-59 who were either usual residents of the households in the GDHS sample or visitors present in the household the night before the survey were eligible to be interviewed in the survey.

Three questionnaires were used for the 2003 GDHS: the Household Questionnaire, the Women's Questionnaire, and the Men's Questionnaire. The contents of these questionnaires were based on the model questionnaires developed by the MEASURE *DHS+* programme and were designed to provide information needed by health and family planning programme managers and policymakers. The questionnaires were adapted to the Ghanaian situation and a number of questions pertaining to ongoing health, HIV, and family planning programmes were added. These questionnaires were translated from English into the five major languages (Akan, Nzema, Ewe, Ga, and Dagbani). The questionnaires are attached in Appendix E.

The Household Questionnaire was used to list all the usual members and visitors in the selected households. Information was collected on the characteristics of each person listed, including the age, sex, education, and relationship to the head of household. The main purpose of the Household Questionnaire was to identify eligible women and men for the individual interview. The Household Questionnaire collected information on characteristics of the household's dwelling unit, such as the source of drinking water, type of toilet facilities, flooring materials, ownership of various consumer goods, and ownership and use of mosquito nets. It was also used to record height and weight measurements of women 15-49 and children under the age of 5, and to record the respondents' consent to the haemoglobin and HIV testing.

The Women's Questionnaire was used to collect information from all women age 15-49. These women were asked questions on the following topics: respondent's background characteristics, such as education, residential history, media exposure, knowledge and use of family planning methods, fertility preferences, antenatal and delivery care, breastfeeding and infant and child feeding practices, vaccinations and childhood illnesses, childhood mortality, marriage and sexual activity, woman's work and husband's background characteristics, and awareness and behaviour regarding AIDS and other STIs.

The Men's Questionnaire was administered to all men age 15-59 in every household in the GDHS sample. The Men's Questionnaire collected much of the same information found in the Women's Questionnaire, but was shorter because it did not contain a reproductive history or questions on maternal and child health and nutrition.

1.7   HAEMOGLOBIN AND HIV TESTING

In all households selected for the 2003 GDHS, women age 15-49 and children under age 5 were tested for anaemia. In addition, all eligible women and men were tested for HIV. Anaemia and HIV testing were only carried out if consent was provided by the respondents and in the case of a minor, by the parent or guardian. The protocol for haemoglobin and HIV testing was approved by the Ghana Health Service Ethical Review Committee in Accra and the ORC Macro Institutional Review Board in Calverton, Maryland, USA.

1.7.1 Haemoglobin Testing

Haemoglobin testing is the primary method of anaemia diagnosis. In the GDHS, testing was done using the HemoCue system. A consent statement was read to the eligible woman and to the parent or responsible adult for young children and women age 15-17. This statement explained the purpose of the test, informed prospective subjects tested and/or their caretakers that the results would be made available as soon as the test was completed, and also requested permission for the test to be carried out, as well as the consent to report their names to health personnel in the local health facility if their haemoglobin level was low (severe).

Before the blood was taken, the finger was wiped with an alcohol prep swab and allowed to air-dry. Then the palm side of the end of a finger (in case of adults and children six months of age and older) was punctured with a sterile, non-reusable, self-retractable lancet and a drop of blood collected on a HemoCue microcuvette and placed in a HemoCue photometer, which displays the result. For children under six months of age (or for children under one year of age who were particularly undernourished and bony) a heel puncture was made to draw a drop of blood. The results were recorded in the Household Questionnaire, as well as on a brochure, which was given to each woman, parent, or responsible adult, that explained what the results meant. For each person whose haemoglobin level was low (severe), and who agreed to have the condition reported, a referral was given to the respondent to be taken to a health facility.

1.7.2 HIV/AIDS Testing

All eligible women and men who were interviewed were asked to voluntarily provide a few drops of blood for HIV testing. The protocol for the blood specimen collection and analysis was based on the anonymous linked protocol developed for DHS. The protocol allows for the merging of the HIV results to the socio-demographic data collected in the individual questionnaires, provided that information that could potentially identify an individual is destroyed before the linking takes place. This required that identification codes be deleted from the data file and that the back page of the Household Questionnaires that contain the bar code labels and names of respondents be destroyed prior to merging the HIV results with the individual data file.

If, after explaining the procedure, the confidentiality of the data, and the fact that the test results would not be made available to the subject, a respondent consented to the HIV testing, a dried blood spot (DBS) specimen was obtained from a finger prick. Each respondent who consented to being tested for HIV was given an information brochure on AIDS, a list of fixed sites providing voluntary counseling and testing (VCT) services throughout the country, and a voucher to access free VCT services at any of these sites for the respondent and/or the partner.

Each DBS sample was given a bar code label, with a duplicate label attached to the Household Questionnaire on the line showing consent for that respondent. A third copy of the same bar code label was affixed to a Blood Sample Transmittal Form in order to track the blood samples from the field to the laboratory. Filter papers were dried overnight in a plastic drying box, after which the nurse packed them in individual Ziploc bags for that particular sample point. Blood samples were periodically collected in the field along with the completed questionnaires and transported to the GSS headquarters in Accra for logging in, after which they were taken to the Noguchi Memorial Institute for Medical Research (NMIMR) at Legon, for HIV testing.

In preparation for carrying out the HIV testing, a consultant from the Kenya Medical Research Institute was contracted by ORC Macro to spend a couple of weeks at NMIMR to assess their equipment and staff capacity. In addition, an ORC Macro official worked with laboratory scientists at NMIMR to conduct a validation study and set up the dried blood spot methodology to test for HIV using two Enzyme-Linked Immunosorbent Assay (ELISA) tests from different manufacturers that would also allow for sero-typing.

Several meetings with ORC Macro staff, NMIMR staff, and staff of GSS, were then held to discuss the monitoring of sample collection in the field, the collection of samples from the field, and the delivery of the samples to the laboratory, with built-in checks to verify the samples collected and delivered. It was also emphasized at the meeting that the period between the collecting of blood samples in the field and the time of refrigeration should not exceed 14 days. The DBS filter paper samples with bar codes were received by NMIMR. Upon receipt, the samples were counted and checked against the transmittal sheet to verify the bar code identifications and kept in a cold room at 4 degrees centigrade until testing was started in September.

Samples were taken out of the cold room and kept for at least 30 minutes at room temperature before testing. One-quarter-inch disks were punched from the dried blot spots and were submerged in phosphate buffered saline and Tween 20 for overnight elution at 4 degrees centigrade. The following day, serum was eluted and appropriate dilutions were made according to the testing protocol for the test kits used in the GDHS. These dilutions were determined following the validation study on the same test kits for both the DBS and venous blood samples. Eluted serum was tested following the manufacturer's recommendations for each of the test kits used in the GDHS.

All specimens were tested with a screening test, Vironostika HIV Uni-Form Plus O (ELISA I). All samples positive on the first screening test as well as 10 percent of the negatives were further tested in parallel with Wellcozyme HIV-1 Recombinant and Murex HIV-2 (ELISA II) for serotyping. Results for all the ELISAs were obtained by relating the absorbance value or optical density (OD) of a specimen to the OD of the serum controls. According to the testing algorithm, samples positive on the first ELISA and positive on both the second ELISAs were regarded as postivie for HIV-1 and HIV-2; samples positive on the first ELISA and positive on Wellcozyme HIV-1 Recombinant and negative on Murex HIV-2 were categorized as positive for HIV-1; similarly, samples that were positive on the first ELISA and negative on Wellcozyme HIV-1 Recombinant and positive on Murex HIV-2 were categorized as positive for HIV-2. Samples negative on the first ELISA and negative on ELISAs for serotyping were regarded as negative. Samples that had discordant results on ELISA I and ELISA II were tested again with ELISA I and ELISA II.

The results were obtained and interpreted in the same manner as indicated above for the repeat ELISA testing. Discordant samples from the repeat ELISAs, were tested with a confirmatory test, PEPTI-LAV 1-2. In addition, all samples that tested positive on ELISAs and samples whose repeat ELISA results were discordant were also tested with PEPTI-LAV 1-2. Samples with "grey zone" or discordant results on the two assays (i.e., repeat ELISA's and PEPTI-LAV 1-2) were tested by immunoblotting (Western Blot) with NEW LAV-BLOT I and NEW LAV-BLOT II using appropriate interpretative criteria based on the test kit. There were some indeterminate samples from the first round of testing that were also included for immunoblotting. The result on immunoblotting (Western Blot) was regarded as the final result.

1.8   PRETEST, TRAINING, AND FIELDWORK

1.8.1   Pretest

A pretest of the Household, Women's, and Men's questionnaires used in the GDHS was conducted in May 2003 in English and five major local languages. The pretest training was conducted by GSS staff for two weeks from 5-17 May 2003. In addition, nurses recruited from the Ghana Health Service were trained in testing for haemoglobin and collecting blood samples for HIV/AIDS. Five teams were formed to conduct the pretest. Each team consisted of a supervisor, four interviewers, and a nurse. Urban and rural areas were chosen for the pretest to get a better overall sense of the response level and acceptance of HIV/AIDS testing. The lessons learned from the pretest were used to finalize the survey instruments and logistical arrangements.

1.8.2   Training and Fieldwork

A total of 102 interviewers, 23 nurses, and 12 data entry operators participated in the main survey training that took place from 6-27 July 2003. All participants were trained in interviewing techniques and the contents of the GDHS questionnaires. The training was conducted following the standard DHS training procedures, including class presentations, mock interviews, and tests using the Household, Women's, and Men's Questionnaires. All interviewers were trained in taking height and weight measurements. In addition to interviewer training, 23 persons (most of whom were nurses from the Ghana Health Service) were trained for a period of 10 days in anaemia testing, collection of blood samples for the HIV testing, and in informed consent procedures. An additional 20 interviewers were also trained in blood collecting techniques. In addition to in-class practice, the nurses were taken to the local health clinic to practice blood-collecting techniques on women, men, and children.

Interviewers and nurses were selected based on their in-class participation, performance in the field practices, fluency in the Ghanaian languages, and assessment tests. The most experienced trainees, those who took part in the pretest, and those who did extremely well, were selected to be supervisors and editors. Trainees selected as supervisors and field editors were given an additional two-days training on how to supervise fieldwork and edit questionnaires. In addition, there was one standby supervisor and nine interviewers ready for relief assignment whenever necessary. Ten regional statisticians acted as regional coordinators, and GSS staff coordinated and supervised fieldwork activities.

Fifteen teams were constituted for data collection. Each team was made up of a supervisor, an editor, a nurse, four interviewers, and a driver. Fieldwork lasted for three months from late July to late October.

ORC Macro provided technical assistance on all aspects of the survey; staff from ORC Macro participated in field supervision of interviews, height and weight measurements, and blood sample collection.

1.9   DATA PROCESSING

The processing of the GDHS results began shortly after the fieldwork commenced. Completed questionnaires were returned periodically from the field to the GSS headquarters in Accra, where they were entered and edited by data processing personnel who were specially trained for this task. Twelve data entry operators from GSS were trained for one week on data entry procedures using CSPro. All data were entered twice (100 percent verification). In addition, tables were run periodically to monitor the quality of the data collected. The concurrent processing of the data was an advantage for data quality because field coordinators were able to advise teams of problems detected during the data entry. The data entry and editing phase of the survey was completed in mid-December 2003.

1.10   RESPONSE RATES

Table 1.2 shows response rates for the 2003 GDHS. Response rates are important because high non-response may affect the reliability of the results. A total of 6,628 households were selected in the sample, of which 6,333 were occupied at the time of fieldwork. The difference between selected and occupied households is largely due to structures being vacant or destroyed. Successful interviews were conducted in 6,251 households, yielding a response rate of 99 percent.

Table 1.2 Results of the household and individual interviews

Number of households, number of interviews, and response rates, according to residence, Ghana 2003

Result	Residence		Total
	Urban	Rural	
Household interviews			
Households selected	2,720	3,908	6,628
Households occupied	2,571	3,762	6,333
Households interviewed	2,517	3,734	6,251
Household response rate	97.9	99.3	98.7
Interviews with women			
Number of eligible women	2,500	3,449	5,949
Number of eligible women interviewed	2,374	3,317	5,691
Eligible woman response rate	95.0	96.2	95.7
Interviews with men			
Number of eligible men	2,063	3,282	5,345
Number of eligible men interviewed	1,903	3,112	5,015
Eligible man response rate	92.2	94.8	93.8

In the households interviewed in the survey, a total of 5,949 eligible women age 15-49 were identified; interviews were completed with 5,691 of these women, yielding a response rate of 96 percent. In the same households, a total of 5,345 eligible men age 15-59 were identified and interviews were completed with 5,015 of these men, yielding a male response rate of 94 percent. The response rates are slightly lower for the urban than rural sample, and among men than women. The principal reason for non-response among both eligible women and men was the failure to find individuals at home despite repeated visits to the household. The lower response rate for men reflects the more frequent and longer absences of men from the household, principally related to their employment and life style.

Response rates for the HIV testing component were lower than those for the interviews. Details of the HIV testing response rates are discussed in Chapter 13.

HOUSEHOLD POPULATION AND HOUSING CHARACTERISTICS

2

This chapter provides a descriptive summary of the social, economic, and demographic characteristics of households sampled in the survey with a focus on some basic background characteristics such as age, sex, education, place of residence, and socio-economic condition of households. This information is crucial for the interpretation of key demographic and health indicators from which to draw meaningful policies and programmes for intervention. This information is also a basis for gauging the representativeness of the survey.

The basic characteristics of the sampled population, that is, age, sex, education, and place of residence, form the basis of the background information by which most key demographic and health indices are analysed throughout this report. New to the DHS in general, and the 2003 GDHS in particular, is the wealth quintile, which is an indicator of the level of wealth that is consistent with expenditure and income measures. The wealth quintile was constructed using information on household ownership of a number of consumer items, ranging from a television to a bicycle or car, as well as dwelling characteristics, such as source of drinking water, sanitation facilities, and type of material used for flooring. Each asset was assigned a weight (factor score) generated through principal components analysis, and the resulting asset scores were standardised in relation to a normal distribution with a mean of zero and standard deviation of one. Each household was then assigned a score for each asset, and the scores were summed for each household; individuals were ranked according to the total score of the household in which they resided. The sample was then divided into quintiles from one (lowest) to five (highest). A single asset index was developed for the whole sample; separate indices were not prepared for the urban and rural population.

In the 2003 GDHS, a household is defined as a person or a group of persons, related or unrelated, who live together in the same house or compound, share the same housekeeping arrangements, and are catered for as one unit. The Household Questionnaire was used to collect information on all usual residents and visitors who spent the night preceding the survey in the household. This mode of data collection allows the analysis of either the de jure (usual residents) or de facto (those who are present at the time of the interview) populations.

2.1 HOUSEHOLD POPULATION BY AGE AND SEX

Age and sex are important variables in analysing demographic trends. Table 2.1 presents the distribution of the de facto household population in the 2003 GDHS survey by five-year age groups, according to sex and urban-rural residence. Figure 2.1 and Table 2.1 show the population by sex for Ghana. The data show that there are slightly more women (53 percent) than men (47 percent) in the overall population. There is a slightly higher concentration of women in the urban than rural areas (55 and 51 percent). The age structure is typical of a young population characterised by high fertility. This type of population structure imposes a heavy burden on the social and economic assets of a country. Ghana's population is still young, with 44 percent of the population under 15 years, with the percentage in the older age groups (65 years and above) constituting just 5 percent of the population.

Figure 2.1 **Population Pyramid**

GDHS 2003
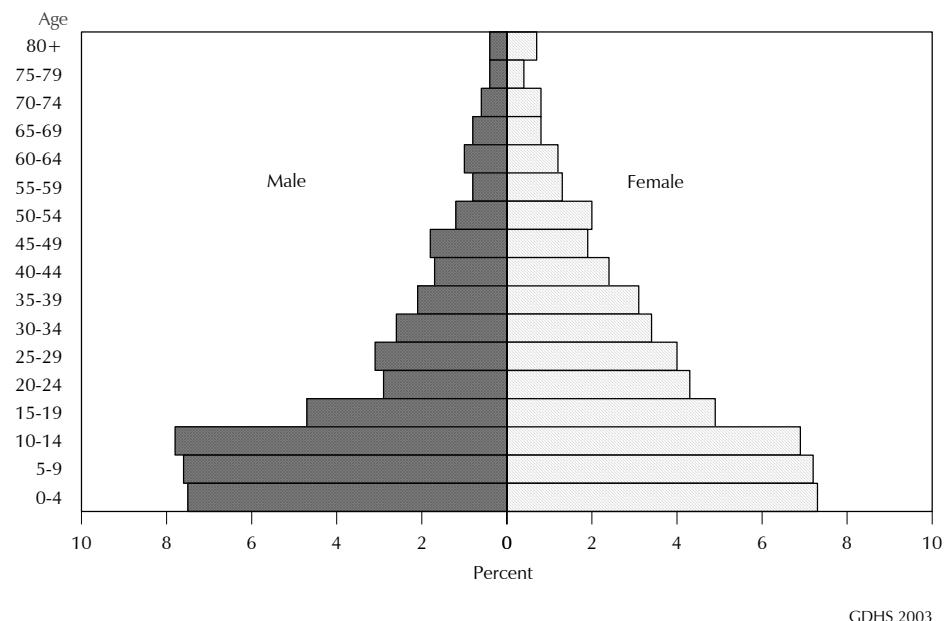

Table 2.1 Household population by age, sex, and residence

Percent distribution of the de facto household population by five-year age groups, according to sex and residence, Ghana 2003

Data from the GDHS show an excess of males in the 10-14 age group, and a deficit in the 20-24 and 40-44 age groups. The excess of males in the 10-14 age group could be the effect of age shifting by interviewers in the DHS, out of the eligible age range (15-59) for the individual interviews, to reduce their workload. This effect is also obvious for females in the 50-54 age group, who are not eligible for the individual interview. The deficit of males in the 20-24 and 40-44 age groups is also reflected in the 2000 Census (GSS, 2002), and may be attributable to differential outmigration of males in search of jobs.

2.2   HOUSEHOLD COMPOSITION

The size and composition of households and the sex of the head of household are important aspects that impact on household welfare. Table 2.2 shows information collected in the 2003 GDHS on sex composition and household size. The mean household size is 4.0, with household size in rural areas (4.3) larger than in urban areas (3.6).

Two-thirds (66 percent) of households are headed by males, while a third (34 percent) are headed by females. The percentage of female-headed households is higher in urban (40 percent) than in rural areas (29 percent).

Single-person households are more common in urban (25 percent) than rural areas (18 percent). This may be due to an influx of unmarried young persons migrating to urban areas in search of employment or to further their education.

dents.

2.3   EDUCATIONAL ATTAINMENT OF HOUSEHOLD MEMBERS

Education is important in that it helps individuals to make informed decisions that impact their health and well-being. Ghana's system of education has undergone several stages of restructuring over the past 25 years (Sedgwick, 2000). The current system of formal education was introduced in 1989. It is based on a three-tier system: six years of primary education, followed by three years of junior secondary school (JSS), and a further three years at the senior secondary school (SSS) level. From the mid-1970s till the introduction of the current system of education, the six years of primary education was followed by five years of secondary education—three years of JSS and two years of SSS. Prior to the mid-1970s, students who completed six years of primary education had a choice. They could attend four years of middle school or attend five years of secondary school with a small group having the further option to pursue an additional two years of pre-university education. Upon completion of formal schooling, a student could choose to further his or her education at the tertiary level. In addition to university education, there are a host of institutions offering vocational, technical, and professional training that may be tertiary or non-tertiary. The different systems of formal education have been taken into account in tabulating the educational attainment of women and men interviewed in the 2003 GDHS.

Table 2.3.1 shows the percent distribution of the de facto female household population age six years and over by highest level of education attended or completed, according to background characteristics. Thirty-seven percent of women have never been to school, about 30 percent have some primary or have completed primary school, 31 percent have some secondary or have completed secondary school, and about 2 percent have more than secondary school education.

The data reveal that the proportion of women with no education is higher among older women, suggesting some improvement in education over the years. This may be due to the impact of the Free Compulsory Universal Basic Education (fCUBE) programme introduced in 1996. Education varies by place of residence. Urban women are more likely to be educated than rural women. For example, 26 percent of urban females have no education, compared with 47 percent of rural females. The proportion of urban females with some secondary education or higher (47 percent) is more than twice as high as that of rural females (21 percent).

It is notable that females in the northern half of the country (Northern, Upper East, and Upper West regions) are seriously disadvantaged educationally. More than two-thirds of women in these regions have never been to school, compared with one-fifth in the Greater Accra region. In addition, 13 percent of females in Greater Accra have completed secondary education or higher, compared with less than 2 percent in the Northern and Upper West regions. With the exception of the three northern regions, the majority of females in all regions have been to school.

It is worth noting that the proportion of female household members who have never attended school decreases with higher wealth status. Sixty-five percent of women in the lowest wealth quintile have no education compared with only 15 percent in the highest quintile.

Table 2.3.2 shows that 26 percent of males have never been to school, 33 percent have had some primary or have completed primary education, 37 percent have had some secondary or completed secondary education, and about 4 percent have more than secondary education. One-third of males in rural areas have no education compared with only 15 percent in urban areas. There is a marked urban-rural differential in secondary and higher education: 16 percent of males in urban areas have completed secondary or higher education compared with only 4 percent in rural areas.

[1] Completed grade 6 at the primary level
[2] Completed grade 12 at the secondary level

Across the regions the pattern among the male population is similar to that exhibited by the females. Males in the three northern regions are disadvantaged, with 54-59 percent never having been to school compared with less than 20 percent in the other regions, except Brong Ahafo (24 percent) and the Central (21 percent) regions. The variation in education among the male population according to wealth quintile is similar to that among the female population. Wealthy males are less likely to have no education. For example, 7 percent of males in the highest wealth quintile have no education compared with 53 percent in the lowest.

[1] Completed grade 6 at the primary level
[2] Completed grade 12 at the secondary level

Men are more educated than women at all levels of education, implying that females continue to lag behind males in education. The median number of years of schooling completed is twice as high among men (3.9 years) as among women (2.1 years). It is disappointing to note that the level of education has deteriorated over the last five years for both women and men. The proportion of women with no education rose from 34 percent in 1998 (GSS and MI, 1999) to 37 percent in 2003, with the median number of years of schooling falling slightly from 2.3 to 2.1 over the five years. Similarly, the proportion

of men with no education rose from 21 percent (GSS and MI, 1999) to 26 percent with the median number of years of schooling falling from 4.9 to 3.9 over the last five years. Nevertheless, the male-female gap in educational attainment has narrowed over the same period.

The 2003 GDHS collected information on school attendance among the population 6-24 years that allows the calculation of net attendance ratios (NARs) and gross attendance ratios (GARs). The NAR for primary school is the percentage of the primary-school-age (6-11 years) population that is attending primary school. The NAR for secondary school is the measure of the secondary-school-age (12-18 years) population that is attending secondary school. By definition, the NAR cannot exceed 100 percent. The GAR however, measures participation at each level of schooling among persons age 6-24. The GAR is almost always higher than the NAR for the same level because the GAR includes participation by those who may be older, because they may have started school late, may have repeated one or more grades in school, or may have dropped out of school and later returned, or may be younger than the official age range for that level.

Table 2.4 presents data on NAR and GAR for the de jure household population by level of schooling and sex, according to place of residence and wealth quintile. Sixty percent of children age 6-11, who should be attending primary school, are currently doing so. At the same time, the GAR at the primary school level is 95 percent, indicating that more than a third (35 percent) of young Ghanaians attending primary school are above or below primary school age. Not surprisingly, both the NAR and GAR are much lower at the secondary than at the primary school level. Slightly more than one-third of students age 12-18 who should be attending secondary school are in school at that level. The GAR for secondary school is 41 percent, indicating that the proportion of underage or overage youths in secondary school is not so large. The results show similar proportions of NAR for females and males at primary and secondary school level, indicating that there is no gender gap in school attendance among the Ghanaian school age population who should be attending school at a given level. However, the GARs at primary and secondary school levels are slightly higher for males than females, indicating a relatively higher overage or underage attendance among males than females.

As expected, school attendance ratios at both the primary and secondary levels are lower in rural than in urban areas. For instance, the NAR at the primary school level in rural areas is 56 percent compared with 68 percent in urban areas. Similarly, the GAR at secondary school is 31 percent in rural areas compared with 53 percent in urban areas. Regional differences are obvious for the NAR and GAR with attendance ratios notably lower among the three northern regions (Northern, Upper East, and Upper West) compared with all other regions, and especially in the case of the GAR at the primary school level.

There is a strong relationship between household economic status and school attendance that can be seen at both the primary and secondary levels and among males and females. For example, the NAR increases from 43 percent among students from poorer households (lowest wealth quintile) in primary school to 78 percent among students from richer households (highest wealth quintile). Similarly, the GAR rises three-fold from 20 percent among secondary school attendees in the lowest wealth quintile to 63 percent among those in the highest wealth quintile.

The Gender Parity Index (GPI) represents the ratio of the GAR for females to the GAR for males. It is presented at both the primary and secondary levels and offers a summary measure of gender differences in school attendance rates. A GPI less than 1 indicates that a smaller proportion of females than males attend school. In Ghana, the GPI is slightly less than 1 (0.9) for both primary and secondary school attendance, indicating that the gender gap is relatively small. There are no marked differences in the GPI by place of residence. The Northern Region has the widest gap (0.8) for primary school attendance and the Brong Ahafo Region has the widest gap (0.7) for secondary school attendance.

[1] The NAR for primary school is the percentage of the primary-school age (6-11 years) population that is attending primary school. The NAR for secondary school is the percentage of the secondary-school age (12-18 years) population that is attending secondary school. By definition the NAR cannot exceed 100 percent.
[2] The GAR for primary school is the total number of primary school students, expressed as a percentage of the official primary-school-age population. The GAR for secondary school is the total number of secondary school students, expressed as a percentage of the official secondary-school-age population. If there are significant numbers of overage and underage students at a given level of schooling, the GAR can exceed 100 percent.
[3] The Gender Parity Index for primary school is the ratio of the primary school GAR for females to the GAR for males. The Gender Parity Index for secondary school is the ratio of the secondary school GAR for females to the GAR for males.

Figure 2.2 shows the age-specific attendance rates (ASAR) for the de jure household population age 6-24 by sex. The ASAR shows participation in schooling at any level, from primary through higher education. The closer the ASAR is to 100, the higher the participation of a given age population at that level. Less than 50 percent of children age seven and below are attending school. School attendance rises markedly up to age 11, remains high up to age 14, and then gradually declines. There are no marked differences in the proportion of males and females attending school up to age 15, after which there are significantly higher proportions of males than females attending school.

Figure 2.2 Age-Specific Attendance Rates

GDHS 2003

2.4   HOUSING CHARACTERISTICS

There is a strong correlation between the socio-economic condition of households and the vulnerability of its members, and especially children, to common diseases. The amenities and assets available to households are important in determining the general socio-economic status of the population. The GDHS included questions on a household's access to electricity, source of drinking water, type of sanitation facilities, flooring materials, and ownership of durable goods. Table 2.5 presents the distribution of households by household characteristics, according to residence.

One in two households in Ghana has electricity. Three-fourths of households in urban areas (77 percent) have electricity compared with one-fourth (24 percent) of rural households. The 2003 data show an increase in the use of electricity among rural households over the last five years (GSS and MI, 1999), while access to electricity in urban households has declined over the same time period. The decline in the use of electricity by urban households may be attributed to the rapid development in housing projects, some of which are not yet connected to the national power grid.

The availability of and accessibility to potable water may, to a large extent, minimise the prevalence of water-borne diseases among household members, especially young children. The source of drinking water is important because potentially fatal diseases, such as diarrhoeal diseases, guinea worm, bilharzia, typhoid, cholera, and dysentery, are common in the country. The main sources of drinking water are piped, protected well or borehole, and rivers or streams. Sixteen percent of households have

access to piped water in their dwelling, yard or plot, while 23 percent access drinking water from a public tap. Twelve percent of households get their drinking water from open wells, and 28 percent obtain drinking water from protected wells or boreholes. Fourteen percent of households obtain drinking water from rivers and streams. Not surprisingly, rural households have less access to clean drinking water than urban households. For example, one in three urban households have piped water in their dwelling, yard or plot, compared with 2 percent of rural households. The major source of drinking water for rural households is a well or borehole. For example, two-fifths of rural households get their drinking water from a protected public well or borehole, compared with one-tenth of urban households. The overall access to piped drinking water has remained the same over the last five years (GSS and MI, 1999). It takes eight in ten urban households and about half of rural households less than 15 minutes to reach their nearest source of drinking water. The median time to source in urban households is 4 minutes compared with 14 minutes among rural households. The vast majority of households have access to water all the time. Rural households are more likely than urban households to have access to water all the time.

The availability of toilet facilities in households ensures a more efficient and hygienic method of human waste disposal. Most households in Ghana (42 percent) have traditional pit latrines, 26 percent have improved ventilated pit latrines (KVIP), and 11 percent have flush toilets. One-fifth of households have no toilet facility. Lack of a toilet facility is more common in rural areas (31 percent) than in urban areas (7 percent). Two-fifths of urban households have KVIP toilets, compared with 14 percent of households in rural areas. Traditional pit toilets are twice as common in rural areas (54 percent) as in urban areas (27 percent). Flush toilets are more common in urban households

Continued…

(21 percent) than in rural households (2 percent). Access to flush toilets has risen over the last five years, from 8 percent in 1998 (GSS and MI, 1999) to 11 percent in 2003. The majority of households (69 percent) share toilet facilities with one or more households.

The type of flooring material used in dwellings is a proxy indicator of the socio-economic status of the household as well as its likely exposure to disease-causing agents. Most households in Ghana (87 percent) have finished floors (terrazzo, tiles, cement, carpet, and linoleum), with only 12 percent of households having rudimentary or natural flooring material (earth, sand, mud or mud mixed with dung). There has been little change over the last five years in the percentage of households with finished flooring. Rural households are much more likely to have cement floors (72 percent) than urban households (55 percent). The second most common flooring material in rural areas is earth, sand, or mud (18 percent). About one-fifth of urban households have linoleum floors and almost the same proportion have carpeted floors.

Two common sources of cooking fuel in the country are firewood (59 percent) and charcoal (30 percent). One in four urban households uses firewood, while 87 percent of rural households depend on firewood as their main source of cooking fuel. On the other hand, more than 50 percent of urban households use charcoal compared with 10 percent of rural households. Liquified petroleum gas (LPG) or natural gas is used more commonly by urban households (15 percent) than households in rural areas (1 percent). However, even in urban areas, few households use electricity for cooking (1 percent), presumably because of the higher cost.

HIS = Health Insurance Scheme

The GDHS also included questions pertaining to disposal of household waste, possibility of eviction, and membership in mutual health organisations (MHO) or health insurance schemes (HIS). Data on these are also shown in Table 2.5. The majority of households (62 percent) dispose of their household waste in the street or an empty plot, with a much higher proportion of rural households than urban households disposing of household waste in this manner. Fourteen percent of households have their waste collected by the government and this is predominantly done in urban areas. Seven percent of households burn their waste, 4 percent have their waste collected by a community association, 4 percent dump it in their compound, while 3 percent each bury or compost their household waste.

When asked about the possibility of eviction, most household respondents said that this was not likely at all (71 percent). Twelve percent of households mentioned that it was very likely that they could

be evicted, while 15 percent of households mentioned that it was somewhat likely. Urban households are more likely to report that they face possible eviction than rural households. A very small percentage of households in Ghana (3 percent) belong to an HIS. Among those who belong to an HIS, the majority belong to an MHO (43 percent) or have government health coverage (20 percent), with 29 percent belonging to a private health insurance scheme (data not shown). About half of those who belong to any kind of insurance scheme mentioned that they have benefited from it in the past, and a large majority (91 percent) of those who are not members of an insurance scheme indicate that they would consider joining one in the future (data not shown).

2.6   HOUSEHOLD DURABLE GOODS

Respondents were asked about ownership of particular household goods such as radios and television sets (access to media), refrigerators (access to food storage), telephones (access to other means of communication), and modes of transport (bicycle, motorcycle, car, or truck). Ownership of these items is also indicative of the household's social and economic well-being. Table 2.6 presents data on the percentage of households possessing various durable consumer goods, by residence. The results show that 71 percent of households own a radio, 26 percent have a television, 23 percent have bicycles, and 19 percent own refrigerators. It is striking to note that nearly one in four households possess none of the durable items identified. There has been a noticeable rise in ownership of consumer durable goods over the last five years, with the most marked increase in the ownership of refrigerators, which increased from 2 percent in 1998 (GSS and MI, 1999) to 19 percent in 2003.

Table 2.6 Household durable goods

Percentage of households possessing various durable consumer goods, by residence, Ghana 2003

Durable consumer goods	Residence		
	Urban	Rural	Total
Radio	76.1	66.6	71.0
Television	44.9	9.9	26.0
Telephone	14.3	0.7	6.9
Refrigerator	34.6	5.5	18.8
Video deck	20.6	2.2	10.6
Bicycle	16.0	29.1	23.1
Motorcycle	2.6	1.7	2.1
Car/truck	9.0	2.4	5.4
Tractor	0.4	0.2	0.3
Horse/cart	0.3	1.4	0.9
None of the above	18.3	27.1	23.1
Number of households	2,870	3,381	6,251

Sixty-seven percent of households in rural areas have a radio. Smaller proportions, however, own consumer items such as televisions, telephones, refrigerators, and cars. Twenty-nine percent of rural households own bicycles, compared with 16 percent of urban households. Televisions, refrigerators, telephones, and cars or trucks are mostly restricted to urban areas, presumably due to the lack of electricity or affordability in rural areas.

CHARACTERISTICS OF SURVEY RESPONDENTS $\qquad$ 3

The purpose of this chapter is to provide a descriptive summary of the demographic and socio-economic profile of respondents in the 2003 GDHS. This basic information on women and men in the reproductive age group is crucial for the interpretation of the 2003 GDHS findings within the context of reproduction, health, and women's status and empowerment. The percent distribution of respondents by the various demographic and socio-economic characteristics can also be used as an approximate indicator of the representativeness of the survey sample to the general population. The main background characteristics described in detail that will be used in subsequent chapters on reproduction and health are: age at the time of the survey, marital status, residence, education, and wealth quintiles. This chapter also includes information on literacy, exposure to mass media, employment and earnings, and women's position and decisionmaking power in relation to others in the household.

3.1 BACKGROUND CHARACTERISTICS OF RESPONDENTS

Table 3.1 shows data on the background characteristics of the 5,691 female respondents age 15-49 and the 5,015 male respondents age 15-59, interviewed in the 2003 GDHS, by background characteristics, including age, marital status, urban-rural residence, region, education, religion, and ethnicity.

The age distribution shows that more than one in two females (55 percent) and males (51 percent) are under age 30. The proportion in each age group tends to decrease with increasing age for both sexes. The data show that most of the respondents are currently married or living together, although the proportion of women (62 percent) who are married or living together is higher than men (53 percent). Four in ten men (41 percent) have never married, compared with only about three in ten women (28 percent). Nine percent of women and 6 percent of men are divorced, separated, or widowed.

The distribution of respondents by urban-rural residence shows that men are slightly more likely to live in rural areas (55 percent) than women (52 percent). By region, the distribution of respondents varies markedly. For example, about one-fifth of respondents are from the Ashanti Region, about one-sixth are from Greater Accra, and about one-tenth each are from the Western, Eastern, Brong Ahafo, and Northern regions. Less than 3 percent of women and men are from the Upper West Region.

Twenty-eight percent of women and 18 percent of men have no education. About one-fifth of women and one-sixth of men have only primary education and two-fifths have only middle/JSS level of education. Men are twice as likely to have attained the secondary level of education as women (23 and 12 percent, respectively).

The majority of respondents are Christians—77 percent of women and 70 percent of men. Sixteen percent of women and 19 percent of men are Moslems. The ethnic composition shows that Akans are the predominant group, with 51 percent of women and 47 percent of men, followed by the Mole Dagbon (13 percent of women and 18 percent of men).

Note: Education categories refer to the highest level of education attended, whether or not that level was completed.
na = Not applicable

3.2   EDUCATIONAL ATTAINMENT AND LITERACY

Education provides people with the knowledge and skills that can lead to a better quality of life. The level of education has been found to be highly associated with the health of mothers and their children and on their reproductive health behaviours. Tables 3.2.1 and 3.2.2 present the distribution of women and men by highest level of schooling attended or completed, and the median number of years of schooling, according to background characteristics. The data show that 28 percent of women have never been to school, 14 percent have some primary education only, while 6 percent have completed primary education. In addition, 44 percent have some secondary education, 8 percent have completed secondary school, with 3 percent having attained higher than secondary education. The data also show that men are more educated than women at all levels of education. For example, about twice as many men as women have completed secondary education or gone on to a higher level. On average, men have two more years of schooling than women—the median years of schooling among women and men is 6.2 and 8.3 years,

[1] Completed 6 grade at the primary level
[2] Completed 12 grade at the secondary level

respectively. High dropout of girls at primary and secondary levels may explain some of the differences in educational attainment between women and men. The Ghanaian government has been considering measures to enhance girls' retention rates in schools. One such measure allows girls who drop out of school due to pregnancy to continue with their education after delivery.

The data show that the educational attainment among both women and men has improved over time, as seen by the changes between age cohorts. For example, 40 percent of women in the oldest age cohort (45-49) have no education compared with 12 percent among those age 15-19, while the corresponding percentages for men are 35 and 8 percent, respectively.

Tables 3.2.1 and 3.2.2 also show that educational attainment varies greatly by urban-rural residence. Respondents in rural areas have substantially lower levels of educational attainment than their urban counterparts. Forty percent of women and 25 percent of men in the rural areas have never been to school in contrast to 16 percent of women and 8 percent of men in urban areas.

Educational attainment is highest in Greater Accra and lowest in the Northern region. This is not surprising because Greater Accra is the most urbanized region in the country and has better educational opportunities. Nevertheless, even in this region, twice as many women as men have no education.

Not surprisingly, there is a direct relationship between educational attainment and wealth. Women and men in the highest wealth quintile are most educated, in contrast to respondents with little or no education who are concentrated in the lowest wealth quintile. For example, 8 percent of women and 2 percent of men from the highest wealth quintile have no education, in contrast to 64 and 48 percent of women and men, respectively, in the lowest wealth quintile.

Literacy is widely acknowledged as benefiting both the individual and society and, in particular among women, is associated with a number of positive outcomes, including intergenerational health and nutrition benefits. In the 2003 GDHS, literacy was ascertained by a respondent's ability to read none, part, or all of a simple statement in any language that the respondent is likely to be able to read. The questions on literacy were asked only of respondents who had not attended school or attended primary or middle/JSS only. Respondents for whom no card with the required language was available, and those who were blind or visually impaired, are excluded from the estimation of percent literate, because their literacy cannot be gauged.

Tables 3.3.1 and 3.3.2 show the percent distribution of women and men by level of schooling attended and by level of literacy. More than half (55 percent) of women and nearly three-quarters (73 percent) of men are literate, while 45 percent of women and 27 percent of men cannot read at all. As in the case of educational attainment, men are more likely to be literate than women. Forty percent of rural women compared with 71 percent of urban women are literate. Similarly, 62 percent of rural men compared with 87 percent of urban men are literate.

Regional variations in the level of literacy are marked, ranging from a high of 75 percent among women in Greater Accra to a low of 14 percent among women in the Northern region. Almost nine in ten men in Greater Accra (89 percent) are literate, compared with one in three in the Northern and Upper East regions.

There is a strong relationship between wealth and literacy levels. Women (83 percent) and men (95 percent) categorised in the highest wealth quintile are literate compared with only 20 percent of women and 37 percent of men in the lowest wealth quintile. Four in five women and three in five men in the lowest quintile cannot read at all.

Table 3.3.1 Literacy: women

3.3   ACCESS TO MASS MEDIA

The 2003 GDHS collected information on respondents' exposure to both broadcast and print media. This information is a means of assessing the potential effectiveness of using these media to broadcast messages on such important topics as reproductive health and HIV/AIDS. Tables 3.4.1 and 3.4.2 show that access to mass media, especially the broadcast media, is generally high in Ghana. Seventy-four percent of women and 89 percent of men listen to the radio at least once a week, and 44 percent of women and 51 percent of men watch television at least once a week. Exposure to the print

Table 3.4.1 Exposure to mass media: women

media is relatively low. Twelve percent of women and 28 percent of men read a newspaper at least once a week. Men are twice as likely as women to be exposed to all three media sources (23 and 10 percent, respectively).

Media exposure is higher among younger women (age 15-24) than older women (25 years and above). However, among men, exposure is lowest among those age 15-19 and highest among those age 20-29. Urban women and men tend to have greater exposure to all three media sources than their rural counterparts. The high level of illiteracy among rural women is reflected in the lower proportion of these women (4 percent) exposed to the print media than urban women (21 percent).

Table 3.4.2 Exposure to mass media: men

Total	28.4	50.6	89.3	22.9	8.1	5,015

More than one in five women and one in two men in Greater Accra are exposed to all three media sources. Media exposure is markedly lower in the three northern regions and is especially low in the Upper West, where only 1 percent of women and 4 percent of men are exposed to all three media sources. Exposure to mass media is closely related to the level of education of respondents. Half of all women and three-fifths of all men with at least secondary education are exposed to all three media sources. Three-fifths and nearly three-quarters of highly educated women and men read a newspaper at least once a week.

There is a high correlation between wealth and media exposure, with the gap between those in the highest quintile and all other quintiles being especially wide. For example, 30 percent of women in the highest wealth quintile are exposed to all three media compared with 7 percent or less of women in the other four quintiles.

Since 1998, the proportions of both women and men who have no media exposure have declined markedly, from 30 percent to 21 percent among women and 15 percent to 8 percent among men (GSS and MI, 1999). However, the proportion of women and men who report reading the newspaper and watching television at least once a week has declined, while the proportion who reported listening to the radio has increased. Some of these reported differences by type of media source may be due to a change in the way the questions were worded between the two surveys.

3.4 EMPLOYMENT

3.4.1 Employment Status

Tables 3.5.1 and 3.5.2 present the percent distribution of women and men by employment status, according to background characteristics. There is little difference in the overall employment status of women and men. Three-fourths of women and men reported being currently employed, while 3 percent reported being employed in the 12 months preceding the survey, but not employed at the time the survey was fielded. About one-fifth of women and men were not employed in the 12 months prior to the survey.

Current employment increases with age from 33 and 26 percent among the youngest cohort of women and men, respectively, to about 95 percent among the oldest cohort of respondents. Low current employment among young women and men may be due to the fact that a proportionately larger number of young people are still in school. Currently and formerly married women are more likely to be currently employed than never married women. However, among men, married men are more likely to be employed than formerly married men and those never married.

Current employment rises with the number of living children. For example, about one in two respondents with no children are currently employed compared with 94 percent of women and 98 percent of men with five or more children. Current employment is also higher among rural respondents than urban respondents. This could be due to the fact that it is easier to find employment in the largely informal sector in the rural areas than in urban areas. Unemployment could also be higher in the urban areas because there is greater demand for skilled labour, which is harder to acquire.

There is little variation in employment status of respondents by region. More than 80 percent of women in the Upper West and Volta regions and men in the Upper East and Northern regions are currently employed compared with about 70-80 percent of respondents in all other regions.

Current employment is inversely related to education, falling from 86 percent among women with no education to 60 percent among women with at least secondary education. The corresponding data for men is 97 and 67 percent, respectively. A similar pattern is seen by wealth quintile for both women and men.

Table 3.5.1 Employment status: women

Percent distribution of women by employment status, according to background characteristics, Ghana 2003

3.4.2 Occupation

Tables 3.6.1 and 3.6.2 show data on employed women and men by their occupation, according to background characteristics. More than one-third of working women (36 percent) and half of men (50 percent) are employed in the agricultural (Figure 3.1). Four times as many women (42 percent) as men (11 percent) work in sales and services. Sixteen percent of employed women and 23 percent of employed men are skilled manual workers. Three times as many men (10 percent) as women (3 percent) are engaged in professional, technical, and managerial positions.

Occupation varies by age groups. Among women, the proportion engaged in agriculture or in professional, technical, or managerial occupations, increases with age. For example, one in four working women age 15-19 are in agricultural occupations compared with nearly one in two women age 45-49. On the other hand, the proportion engaged in sales and services and in skilled manual labour decreases with age. A similar pattern is observed for men for skilled manual labour only.

A higher proportion of never-married women than ever-married women are engaged in most occupations with the exception of agriculture, which accounts for two in five currently married women who are working compared with more than one in four formerly married women and 12 percent of never-married women. There is no clear pattern in occupation by marital status among men. Among working men, about half of those who are currently or formerly married are engaged in the agricultural sector compared to two in five never-married men. Three-tenths of never-married men are engaged as skilled manual labour, compared with one-fifth of ever married men. There is a direct relationship between the number of living children and agricultural occupation among both women and men. The proportion engaged in agriculture increases with the number of living children. Among women, the proportion engaged in all other occupations is higher among those with no children than among those with one or more children.

Not surprisingly, most working women and men in rural areas are engaged in the agricultural sector, in contrast to women and men in urban areas, who are mostly engaged in sales and service and skilled manual work. Agriculture is the predominant occupation among women in the Northern, Upper East, Brong Ahafo, and Upper West regions. In addition to these regions, the majority of men in the Eastern, Volta, and Central regions are also employed in the agricultural sector. In contrast, the majority of working women living in Greater Accra, Ashanti, and Eastern regions are in sales and service jobs. Among working men, the highest proportions engaged in the professional, technical and managerial, clerical, sales and service, and skilled manual work are from Greater Accra.

Education is related to the type of occupation of respondents. Fifty-nine percent of working women and 83 percent of working men who have never been to school are engaged in agriculture. On the other hand, the majority of women and men with secondary or higher education are employed in non-agricultural occupations. Women and men in the lowest quintile are predominantly engaged in agriculture, while those in the highest wealth quintile are mostly engaged in sales and service, skilled manual, or professional, technical, and managerial work.

3.4.3 Type of Employer, Form of Earnings, and Continuity of Employment

Tables 3.7.1, 3.7.2, and Figure 3.2, present data on women and men by type of employment. The majority of women and men (about 60 percent) who work receive cash earnings. A significant proportion of women (25 percent) and men (30 percent) receive earnings in cash and in-kind. Eight percent of women and 5 percent of men are not paid at all.

Three-quarters of women in both agricultural and non-agricultural occupations are self-employed, 14 percent are employed by a non-family member, and 10 percent are employed by a family member. Three-quarters of employed women work all year, while one in five works seasonally. Most women in both agricultural and non-agricultural occupations work all year; however, one in three women who work in agriculture and 13 percent of women engaged in non-agricultural occupations work seasonally. Similar information was not collected for men.

Table 3.7.1 Type of employment: women

Percent distribution of women employed in the 12 months preceding the survey by type of earnings, type of employer, and continuity of employment, according to type of employment (agricultural or non-agricultural), Ghana 2003

Employment characteristic	Agricultural work	Non-agricultural work	Total

3.4.4 Control Over Earnings and Women's Contribution to Household Expenditures

Women's autonomy is dependent not only on their access to income but also on the amount of control they have over their earnings. Employed women who earn cash were asked about who mainly decides how their income is used. Table 3.8 shows that women in Ghana have considerable autonomy over the use of their earnings. Nearly three-fourths of women who earn cash report that they are solely responsible for decisions on the use of their earnings, while 18 percent report that they jointly decide how the money should be spent either with their husband or someone else. Almost one in ten women stated that they have no say in how their earnings are spent.

Sole decisionmaking rises with age. One in five never-married women have no say in how their earnings are used, while a similar proportion of currently married women report that they make joint decision. There is little difference in sole decisionmaking by the number of children, but joint decisionmaking rises with the number of children women have. On the other hand, there is an inverse relationship between the number of children women have and the percentage who have no say in how their earnings are spent. For example, twice as many women who have no children have no say in how their earnings are spent compared with women with one or more children.

Autonomy over cash earnings is higher among urban than rural women, and relatively high among women residing in Greater Accra, Western, and Upper East regions, and lowest among women in the Central region. Education and wealth exert only a small influence on control over earnings. For example, 78 percent of women with at least secondary education or in the highest wealth quintile compared with 70 percent of women with no education or in the lowest wealth quintile have the sole say in how their earnings are spent.

Table 3.8 Decision on use of earnings and contribution of earnings to household expenditures

Percent distribution of women employed in the 12 months preceding the survey receiving cash earnings by person who decides how earnings are to be used and by proportion of household expenditures met by earnings, according to background characteristics, Ghana 2003

[2] Includes husband

Information on the contribution of respondent's income to household expenditures was also gathered in the 2003 GDHS. It is expected that employment and earnings are more likely to empower women if their earnings are important for meeting the needs of their households. However, often women's income is so small that it can barely meet household needs. Table 3.8 shows that the earnings of very young women (age 15-19) are less likely to contribute a major share of household expenditures than those of older women (20-49). Not surprisingly, working women who are divorced, separated, or widowed tend to contribute to a major portion of household expenditure. Women's contribution to household expenditure increases with the number of children they have. There is little difference between urban and rural women's contribution to household expenditure. The majority of working women in all regions except Upper East, Northern, and Ashanti regions meet half or more or all of household expenditure with their earnings. There is no clear relationship between women's contribution to household expenditure and education or wealth.

Table 3.9 shows the relationship between women's control over their earnings and their contribution to household expenditure by marital status. The table shows that women who are not currently married (that is, those who have never married, or are divorced, separated, or widowed) are somewhat more likely (85 percent) than currently married women (69 percent) to make sole decisions on how their earnings are spent. Nine percent of married women do not have a say in how their earnings are spent, with 8 percent reporting that their husbands alone decide on how their earnings are spent. On the other hand, 11 percent of unmarried women have no say in how their earnings are used. The data also show that among unmarried women earning cash, the greater a woman's contribution to household expenditure, the more likely is she to make sole decisions on how her earnings are spent. Nevertheless, 8 percent of married women who contribute all of their earnings to household expenditure report that their husband or someone else makes sole decisions on how their earnings are spent, whereas only 3 percent of unmarried women who contribute all their earnings to household expenditure report that they have no say in how it is spent.

Table 3.9 Women's control over earnings

[1] Never-married, divorced, separated, or widowed women

3.5   WOMEN'S EMPOWERMENT

In addition to information on women's education, employment status, and control over earnings, the 2003 GDHS collected information from both women and men on other measures of women's empowerment. Respondents were asked about women's role in household decisionmaking, their acceptance of wife-beating, and their opinions about whether a wife can deny sex to her husband for certain specified reasons. Such information provides insight into women's control over their environment and their attitudes towards gender roles, both of which are relevant to understanding women's ability to make independent decisions about their own health care and that of their children's.

3.5.1   Women's Participation in Decisionmaking

In order to assess women's weight in household decisionmaking, women were asked who in their family usually has the final say on five different types of decisions, namely: their own health care, large household purchases, daily household purchases, visits to family or relatives, and what food to cook each day. The percent distribution of women according to the person who usually has the final say in different decisions is shown in Table 3.10. The data are presented separately for women who are currently married and women who have never married or who are divorced, separated, or widowed.

Note: Percentages may not add to 100 due to the exclusion of women with missing information.
[1] Never-married, divorced, separated or widowed women

The data show that the majority of Ghanaian women, irrespective of their marital status, do not have sole authority over any of the five main household decisions. Thirty-one percent of all women, irrespective of their marital status, have no final say in any of the decisions, while 35 percent of women have a final say in all the five decisions (Figure 3.3). Among unmarried women, decisionmaking is highly dominated by someone else (59-66 percent), while among married women, decisionmaking is somewhat dominated by husbands (26-41 percent). Married women also report that decisionmaking is made jointly with their husband (21-38 percent). Especially disconcerting is the fact that most women do not have sole authority over their own health care. Only about one-third of married and unmarried women make sole decisions about their own health care. A third of married women report that their husbands make sole decisions about their health care and three-fifths of unmarried women report that someone else makes

**Figure 3.3 Women's Participation in Decisionmaking:
Number of Decisions in Which Women Participate
in the Final Say, Based on Five Household Decisions**

Number of decisions in which woman participates in final say

GDHS 2003

sole decisions about their health care. One-fifth of married women report that decisions on their own health care are made jointly with their husbands. Forty-one percent of married women report that their husbands alone decide on large household purchases compared with 21 percent of women who report that they alone are the sole decisionmakers on large household purchases, and 30 percent of women who report it to be a joint decision. Among the five decisions, married women seem to have the greatest say over what to cook each day (40 percent), while unmarried women have the greatest say over their own health care (33 percent). Joint decisions with husbands are especially important when it comes to visiting family or relatives (38 percent).

Table 3.11 shows the percentage of women who say that they alone or jointly with someone else have the final say in the five specific household decisions, by background characteristics. More than one-third of women say that they alone or jointly with someone else have the final say in all five decisions. The data show that women's participation in decisionmaking rises with age. Women who are divorced, separated, or widowed are more likely to participate in decisionmaking than currently married women. Decisionmaking among women also rises with the number of children she has, indicating her greater involvement in decisions that may have an impact on the welfare of her children. There are no significant differences in decisionmaking by urban-rural place of residence and women's education. Women's involvement in decisionmaking is highest in the Central region and lowest in the Upper East. Employed women who receive cash earnings are more likely to have a greater say in all five decisions than unemployed women and those who are employed but not for cash. Women in the lowest wealth quintile are least likely to report involvement in all five decisions, but beyond that there is little difference among higher wealth quintiles.

3.5.2 Attitudes toward Wife-beating

Violence against women is receiving considerable attention because it has serious consequences for mental and physical well-being, including their reproductive and sexual health (WHO, 1999). To assess the acceptability of domestic violence, respondents interviewed in the 2003 GDHS were asked whether they thought a husband is justified in hitting or beating his wife for any of the following reasons: if she burns the food, if she argues with him, if she goes out without telling him, if she neglects the children, and if she refuses to have sexual relations with him.

The data on attitude toward wife-beating are shown in Tables 3.12.1 and 3.12.2 for women and men, respectively. Nearly one in two women believe that a husband is justified in beating his wife for at least one of the specified reasons (Table 3.12.1). Thirty-seven percent of women believe that a husband is justified in beating his wife if she neglects the children, while one in three women think wife-beating is justified if a wife goes out without telling her husband, and 30 percent believe that wife-beating is justified if she argues with her husband. Twenty percent and 14 percent of women, respectively, believe that a man is justified in beating his wife if she burns the food or refuses to have sex with him.

Surprisingly, younger women, who are presumably more educated, are more likely than older women to agree with at least one reason for wife-beating. Currently married women are slightly more likely than never-married or formerly married women to accept wife-beating. Women who reside in rural areas and in the more conservative northern regions are much more likely than urban women and women in the other regions to accept wife-beating for at least one reason. As a woman's level of education or wealth rises, she is less likely to agree that wife-beating is justified for any reason. There is no clear relationship between attitudes towards wife-beating and women's employment status or decisionmaking power.

Men were also asked their opinions about wife-beating to understand attitudes that may prompt male violence against women (Table 3.12.2). Interestingly, men (32 percent) are less likely than women (49 percent) to feel that wife-beating is justified for at least one reason, and are much less likely to agree that wife-beating is justified for each of the five specific reasons.

Table 3.12.1 Women's attitude toward wife-beating

Percentage of women who agree that a husband is justified in hitting or beating his wife for specific reasons, by background characteristics, Ghana 2003

Background characteristic	Husband is justified in hitting or beating his wife if she:					Percentage who agree with at least one of the specified reasons	Number of women
	Burns the food	Argues with him	Goes out without telling him	Neglects the children	Refuses to have sex with him

3.5.3   Attitudes toward Refusing Sex

Women's rights and control over their own sexuality are important aspects of their empowerment. In addition, their control over when and with whom they have sex has an impact on their health, especially with respect to the transmission of STIs such as HIV/AIDS. Respondents in the GDHS were asked whether a wife is justified in refusing sex when: she knows that her husband has a sexually transmitted disease; she knows that her husband has sex with other women; she has recently given birth; and when she is tired or not in the mood for sex. Tables 3.13.1 and 3.13.2 show the percentage of women and men who believe that a wife is justified in refusing to have sex with her husband for these specified reasons, by background characteristics.

Sexual autonomy is relatively high among Ghanaian women. Nearly two-thirds of women and men agree that women are justified in denying sex to their husbands for all four reasons, with little variation between women and men by background characteristics. Women and men who reside in rural areas, those who live in the Upper West region, poorly educated respondents, and respondents from the lowest wealth quintile are somewhat less likely than their counterparts to agree that a woman is justified in refusing sex with her husband for all four reasons. There is no clear relationship between women's sexual autonomy and her decisionmaking power or beliefs about wife-beating.

Male respondents in the 2003 GDHS were also asked whether they thought that a husband had the right to take specific actions—get angry and reprimand her, to refuse to give her money or other means of financial support, to use force and have sex with her even if she does not want to, and to have sex with another woman—if his wife refused to have sex with him.

Table 3.14 shows that one in four men agree with at least one of the four specified actions. Fifteen percent of men say it is justifiable for men to get angry and reprimand the wife, 12 percent say it is okay to have sex with another woman, 10 percent say it is justifiable to refuse financial support, and 5 percent say it is acceptable to use force if she refuses to have sex with him. Differences by background characteristics are not large. However, men in the youngest cohort (15-19), rural men, men in the Upper West and Northern regions, men with no education, men who are employed but not for cash, and men in the lowest wealth quintile are less tolerant of women's sexual autonomy than other men.

Table 3.13.1 Women's attitude toward wives refusing sex with husbands

FERTILITY

<div style="text-align: right; font-size: large;">**4**</div>

One of the main challenges facing Ghana in the 1950s was high fertility. Ghana introduced its first Population Policy in 1969 to address the problem of high fertility and escalating growth rates in the face of declining mortality. After 25 years of little progress, the Population Policy was revised in 1994 to include a systematic integration of population in development planning with renewed emphasis on fertility deceleration to keep pace with resource generation. Since then, Ghana has made significant progress in reducing its fertility. An important aspect of the demographic and health surveys conducted in the country has been the collection of birth history information to enhance data availability for monitoring the progress in fertility decline.

This chapter presents the 2003 GDHS results on fertility levels, trends, and differentials. The analysis is based on the birth histories collected from women age 15-49 interviewed during the survey. To obtain this information, women were first asked a series of questions to determine the total number of live births they had in their lifetime. For each live birth, information was then collected on the age, sex, and survival status of the child. For dead children, age at death was recorded. Information from the birth history is used to assess current and completed fertility and to look at other factors related to fertility, including age at first birth, birth intervals, and teenage childbearing.

The following measures of current fertility are derived from birth history data:

- **Age-specific fertility rates** (ASFR) are expressed as the number of births per thousand women in the age group and represent a valuable measure for assessing the current age pattern of childbearing. They are defined in terms of the number of live births during a specified period to women in the particular age group divided by the number of woman-years lived in that age group during the specified period.

- **Total fertility rate** (TFR) is defined as the total number of births a woman would have by the end of her childbearing period if she were to pass through those years bearing children at the currently observed rates of age-specific fertility. The TFR is obtained by summing the age-specific fertility rates and multiplying by five.

- **General fertility rate** (GFR) is the number of live births occurring during a specified period per 1,000 women age 15-44.

- **Crude birth rate** (CBR) is the number of births per 1,000 population during a specified period.

The various measures of current fertility are calculated for the three-year period preceding the survey, which roughly corresponds to the calendar period 2001-2003. A three-year period was chosen because it reflects the current situation, while also allowing the rates to be calculated on a sufficient number of cases so as not to compromise the statistical precision of estimates.

4.1   FERTILITY LEVELS AND TRENDS

4.1.1   Fertility Levels

Table 4.1 presents information on the current fertility levels for Ghana as a whole and for urban and rural areas. The table shows that the prime reproductive years among Ghanaian women are during

their twenties and early thirties. Urban-rural differences in childbearing rates are evident for all age groups, but are especially large in the 20s.

With a TFR of 4.4, Ghana's fertility rate is one of the lowest in sub-Saharan Africa, as the comparison in Figure 4.1 indicates. On average, a Ghanaian woman who is at the beginning of her childbearing years will give birth to 4.4 children by the end of her reproductive period if fertility levels remain constant at the levels observed in the three-year period before the 2003 GDHS. The TFR for rural areas (5.6 births) is more than two births higher than the rate for urban areas (3.1 births).

The general fertility rate is 146. This means that there were 146 births for every 1,000 women during the three-year period preceding the survey. The table also shows a crude birth rate of 33 per 1,000 population for the period under review.

Table 4.1 Current fertility

Age-specific and cumulative fertility rates, the general fertility rate, and the crude birth rate for the three years preceding the survey, by urban-rural residence, Ghana 2003

	Residence		
Age group	Urban	Rural	Total
15-19	42	113	74

GFR	102	188	146
CBR	26.6	36.7	32.6
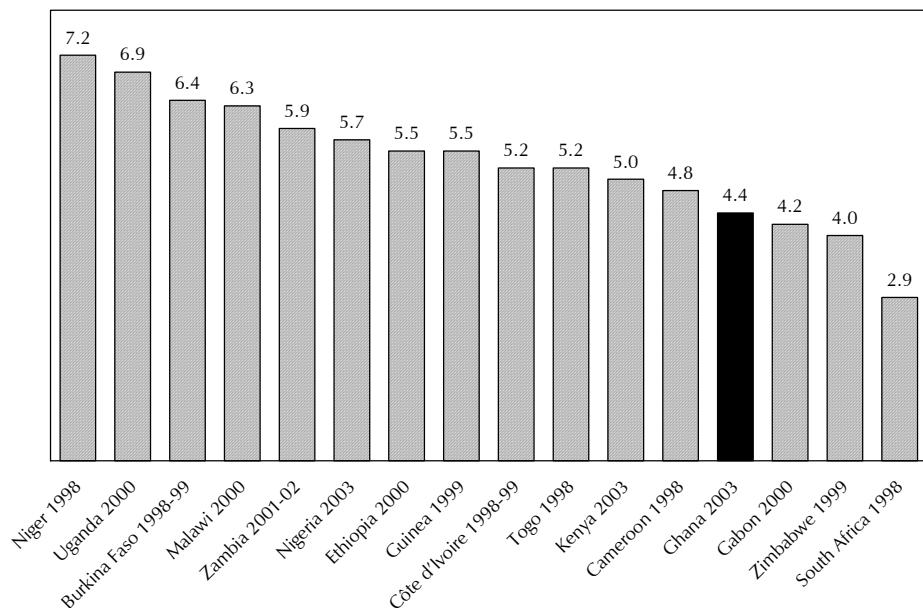

Note: Rates for age group 45-49 may be slightly biased due to truncation.
TFR: Total fertility rate for ages 15-49, expressed per woman
GFR: General fertility rate (births divided by the number of women age 15-44), expressed per 1,000 women
CBR: Crude birth rate, expressed per 1,000 population

Figure 4.1 **Total Fertility Rates, Ghana and Selected Sub-Saharan Countries**

4.1.2 Differentials in Current and Completed Fertility

Table 4.2 presents differentials in the TFR and the percentage of women who are currently pregnant, by key background characteristics. The percentage currently pregnant provides a useful measure of

current fertility. However, it may not capture all pregnant women since some women may be unaware of their pregnancy, or reluctant to disclose a pregnancy in its early stages. The table also shows differentials in the mean number of children ever born to women age 40-49, that is, to women who are at the end of their childbearing years, which is a measure of completed or past fertility. The mean number of children ever born can be compared with the current TFR in order to assess the extent of fertility change over the last two decades in Ghana.

Table 4.2 and Figure 4.2 show that regional variations in fertility are marked, ranging from a high of 7.0 births in the Northern region to a low of 2.9 births in Greater Accra. The TFR is inversely related to the level of education. On average, women with no education (6.0) give birth to more than twice as many children as women with at least secondary education (2.5). Fertility also decreases with increasing wealth, from 6.4 births among women in the lowest wealth quintile to 2.8 births among women in the highest wealth quintile.

Seven percent of women are currently pregnant. Rural women are almost twice as likely to be pregnant at the time of the interview as urban women. Current pregnancy is highest in the Northern region and lowest in Greater Accra. The percentage of women currently pregnant declines as level of education rises and is highest among the poorest segment of women and lowest among the richest.

Table 4.2 Fertility by background characteristics
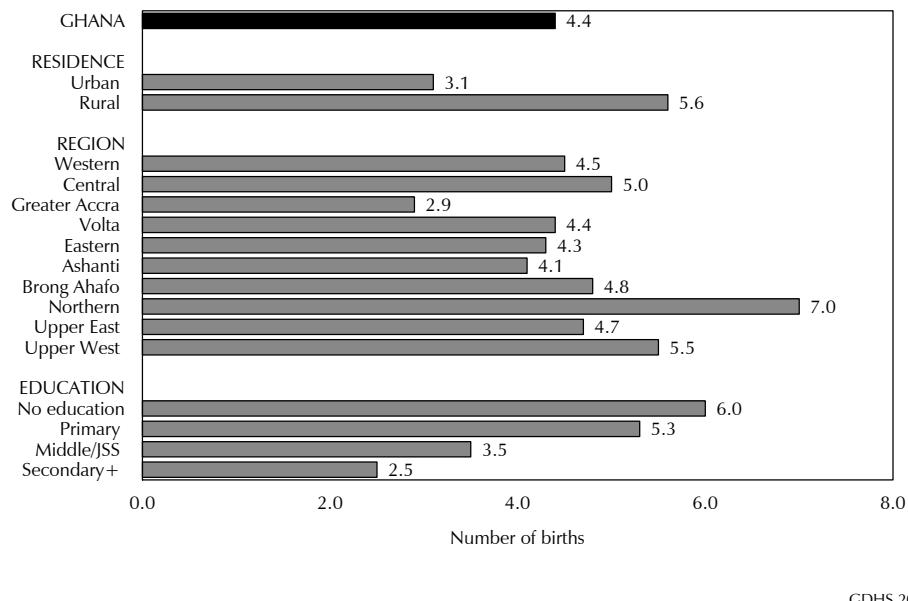

Total fertility rate for the three years preceding the survey, percentage of women 15-49 currently pregnant, and mean number of children ever born to women age 40-49 years, by background characteristics, Ghana 2003

4.1.3   Trends in Fertility

Besides the comparison of current and completed fertility, fertility trends in Ghana can be assessed in several other ways. Fertility trends can be observed using retrospective data from the birth histories collected from respondents in a single survey. The TFR from the 2003 GDHS can also be compared with estimates obtained in earlier surveys or censuses.

Table 4.3 presents the trend in age-specific fertility rates for successive five-year periods before the survey, generated from the birth history data collected in the 2003 GDHS. The numerators of the births are classified by five-year segments of time preceding the survey and the mother's age at the time of birth. Because women 50 years and over were not interviewed in the survey, the rates for older age groups become progressively more truncated for periods more distant from the survey date. For example, rates cannot be calculated for women age 45-49 for the period 5-9 years and more prior to the survey, because women in that age group would have been 50 years or older at the time of the survey. Partially truncated rates are enclosed in brackets in the table.

Table 4.3 Trends in age-specific fertility rates				
Age-specific fertility rates for five-year periods preceding the survey, by mother's age at the time of the birth, Ghana 2003				
	Number of years preceding survey			
Mother's age at birth	0-4	5-9	10-14	15-19
15-19	74	84	117	116
20-24	183	200	228	242
25-29	214	227	253	244
30-34	183	208	233	(239)
35-39	146	162	(201)	
40-44	77	(101)		
45-49	(40)			
Note: Age-specific fertility rates are per 1,000 women. Estimates in brackets are truncated.				

Table 4.3 confirms the substantial decline in fertility over the last two decades. This decline is most obvious in the last three five-year periods preceding the survey, with the largest decline observed between the 10-14 year and 5-9 year periods before the survey. Fertility decline was steepest among the youngest cohort.

A comparison of the TFRs obtained from the three earlier GDHS surveys conducted in 1988, 1993, and 1998, with the TFR obtained from the 2003 GDHS is shown in Table 4.4 and Figure 4.3. Direct estimates of fertility for the three years preceding the survey have been used in this comparison, because a three-year rate is more robust than rates based on a shorter period of time. Hence, these rates may be slightly different from published rates for 1988, 1993, and 1998, which are based on the five years preceding the survey. Fertility trends have to be interpreted within the context of data quality and sample size. A discussion of these issues in relation to earlier surveys is beyond the scope of this report. As such, the fertility trend shown in Figure 4.3 and Table 4.4 should be interpreted with caution. The TFR has declined dramatically from 6.4 children per woman in 1988 to 5.2 children per woman in 1993, and to 4.4 children in 1998, a nearly 2-child drop in fertility over the decade. However, the demographic transition experienced in Ghana in the 1980s and 1990s seems to have slowed in the last three years even though contraceptive use has continued to rise. Further investigation, outside the scope of this report, is necessary to examine the underlying causes for this unexpected trend. Table 4.4 shows that since 1988, fertility has fallen in every age group, with fertility levels among women under age 35 declining by around 25 percent during the decade between the 1988 and 1998 surveys.
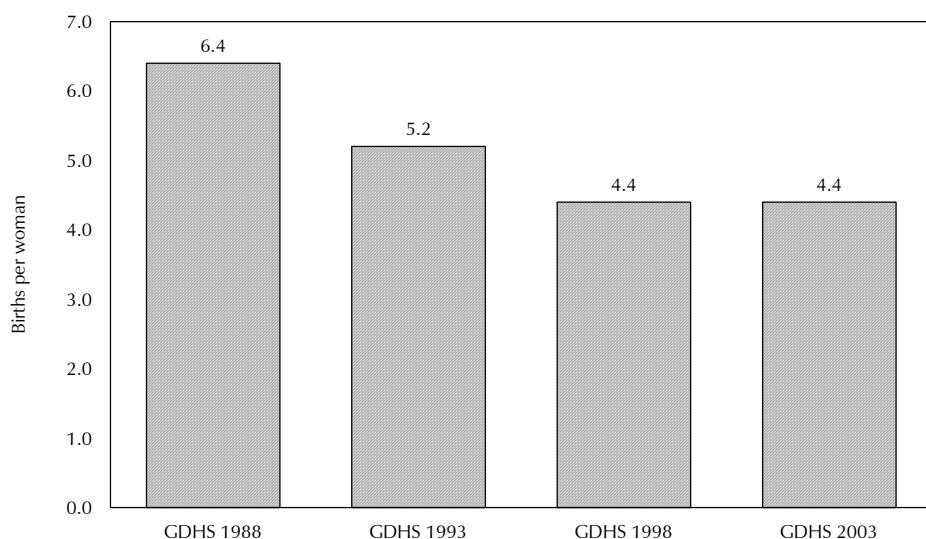

Table 4.4 Trends in fertility

Age-specific fertility rates and total fertility rates for GDHS surveys, 1988-2003

GDHS 1988-2003

4.2   CHILDREN EVER BORN AND CHILDREN SURVIVING

Table 4.5 presents the distribution of all women and currently married women by the mean number of children ever born and the mean number of children surviving, by five-year age groups. Lifetime fertility reflects the accumulation of births over the past 30 years and, therefore, its relevance to the current situation is limited; nevertheless, information on the mean number of children ever born is useful in examining the variation among different age groups.

The distribution of children ever born by age shows that early childbearing is not common in Ghana; nearly 90 percent of women age 15-19 have never given birth. However, this proportion declines to 18 percent for women age 25-29, and to 7 percent or less among women age 30 and older. Ghanaian women attain a parity of 5.9 children by the end of their reproductive age, which is 1.5 children more than the total fertility rate, a difference brought about by the dramatic decline in fertility in the 1980s and 1990s. Although the pattern is similar for currently married women, less than half (44 percent) of women age 15-19 have not borne a child, and this proportion declines rapidly to less than 4 percent by age 30-34. This discrepancy between all women and currently-married women is attributable to the sizeable proportion of young and unmarried women in the former category who exhibit lower fertility. Currently married women reported higher fertility at all ages, and especially at younger ages, and have had an average of 3.5 children compared with 2.5 children among all women. Nevertheless, this one-child difference between currently married women and all women indicates that childbearing outside of marriage is not uncommon in Ghana. Consonant with expectations, the mean number of children ever born and mean number of living children rise monotonically with increasing age of women, thus presupposing minimal or no recall lapse, which heightens confidence in the birth history reports.

Total	7.3	16.1	16.6	16.1	12.1	10.0	8.5	5.5	4.1	2.2	1.5	100.0	3,549	3.54	3.11

Voluntary childlessness is uncommon and currently married women with no live births are likely to be those who are unable to bear children. The level of childlessness among married women at the end of their reproductive lives can be used as an indicator of the level of primary sterility. In Ghana, primary sterility among older currently married women is less than 2 percent.

4.3   BIRTH INTERVALS

Information on birth intervals provides valuable insight into birth spacing patterns. Short birth intervals, that is, births that occur less than 24 months apart, are detrimental to the health of both the mother and her child.

Table 4.6 shows the distribution of non-first births in the five years preceding the survey by the number of months since the previous birth, according to selected demographic and socio-economic variables. First births are omitted from the table because there is no prior birth with which to measure an interval.

Fourteen percent of all non-first births occur less than 24 months after an earlier birth. The median birth interval is 38 months, that is, half of non-first births to women in Ghana occur more than three years after a previous birth. There has been little change in birth spacing patterns over the last five years.

The median birth interval increases with age from 35 months for births to women age 20-29 to 46 months for births to women age 40-49. The longer birth interval among older women may be attributed to the decline in fecundity as women grow older. There are no significant differences in the median birth interval by birth order and sex of the child. However, the median birth interval is markedly shorter if the previous child has died. Among births following a child who has died, 34 percent occur at intervals of less than 24 months. This may be due to the desire of parents to replace dead children, as well as the impact of the loss of the fertility-delaying effects of breastfeeding.

The median interval between births to urban women is seven months longer (44 months) than for rural women (37 months). The median birth interval ranges from a low of 34 months in the Western region to 42 months in Greater Accra and Upper East regions. Education and wealth status are not strongly related to median birth interval, except for births to the most educated and the wealthiest group of women. The median birth interval is longer among non-first births to women with at least secondary education than among women with lower levels of education, and among women in the highest wealth quintile than women in the other wealth quintiles.

Table 4.6 Birth intervals

Note: First-order births are excluded. The interval for multiple births is the number of months since the preceding pregnancy that ended in a live birth. Total includes 6 non-first births to women age 15-19, which are not shown separately.

4.4   AGE AT FIRST BIRTH

One of the factors that determines the level of fertility in a population is the age at first birth. Women who marry early are typically exposed to the risk of pregnancy for a longer period, especially when there is little or no contraceptive use. Thus, early childbearing generally leads to a larger family size than later onset of childbearing. A rise in the median age at first birth is typically a sign of transition from high to low fertility. Table 4.7 shows the percentage of women who have given birth by specific ages and the median age at first birth, according to current age.

Table 4.7 Age at first birth

Percentage of women who gave birth by specific exact ages, and median age at first birth, by current age, Ghana 2003

Current age	Percentage who gave birth by exact age					Percentage who have never given birth	Number of women	Median age at first birth
	15	18	20	22	25			
15-19	0.6	na	na	na	na	89.7	1,148	a
20-24	1.4	14.9	34.6	na	na	47.2	1,012	a
25-29	3.3	22.0	40.8	56.4	76.2	18.1	951	21.1

35-39	4.1	24.2	44.4	64.4	82.1	5.1	722	20.5
40-44	4.4	28.2	48.5	70.8	84.1	2.8	579	20.1
45-49	3.4	24.7	44.9	67.7	85.8	1.6	477	20.4

na = Not applicable
a = Omitted because less than 50 percent of women had a birth before reaching the beginning of the age group

The median age at first birth for the youngest cohort of women age 25-29, for whom a median could be calculated, is 21. For all other age groups, the median age at first birth is around 20 years, suggesting that age at first birth has increased in the most recent period. Further evidence of this trend is observed by the fact that the percentage of first births occurring at age 18 or less has fallen from 25 percent among the oldest cohort of women (age 45-49) to 15 percent among the youngest cohort for whom complete information is available (age 20-24). This reduction in the percentage of women giving birth early implies that more young women are postponing childbearing. A comparison of data from the 1993, 1998, and 2003 GDHS for the same age groups reinforces the conclusion that there has been a trend towards a rising age at first birth.

4.5   MEDIAN AGE AT FIRST BIRTH BY BACKGROUND CHARACTERISTICS

Age at first birth tends to vary by demographic and socio-economic characteristics of women. Table 4.8 shows the median age at first birth among women by selected background characteristics. The median age at first birth for women age 25-49 in Ghana is 20.5 years. Urban women have their first birth a year later than their rural counterparts. Across regions, the median age at first birth ranges from a low of 19.9 years in the Upper East to a high of 21.8 years in Greater Accra.

Age at first birth by education does not appear to vary substantially between education categories, although the median age at first birth for the highest level of education (Middle/JSS) for which a median could be estimated is somewhat higher than that at lower levels. The data also show that women who belong to the wealthiest quintile have their first child about two years later than women in all the other wealth quintiles.

4.6 TEENAGE FERTILITY

Adolescent childbearing has potentially negative demographic and social consequences. Births that occur to teenage mothers (less than 20 years) have been found to have the highest infant and child mortality in Ghana (GSS and MI, 1994 and 1999). This may be due to the fact that teenage mothers are more likely to suffer from pregnancy and delivery complications than older mothers, resulting in higher morbidity and mortality for both themselves and their children. In addition, early childbearing may foreclose a teenager's ability to pursue educational or job opportunities. Table 4.9 shows the percentage of adolescent women (age 15-19) who are mothers or pregnant with their first child, by background characteristics. One in ten teenagers has already had a child (10 percent) and another 4 percent are pregnant with their first child.

Table 4.9 Teenage pregnancy and motherhood

Total	10.3	3.5	13.8	1,148

        Urban teenagers differ substantially from their rural counterparts with respect to childbearing. Seven percent of adolescents in urban areas have begun childbearing, compared with 22 percent of their counterparts residing in rural areas. By region, the percentage of women age 15-19 who have begun childbearing ranges from a low of 10 percent in the Greater Accra, Upper West, and Ashanti regions to a high of 24 percent in the Central and Northern regions. It is also clear that childbearing among adolescents decreases with higher education (26 percent among adolescents with no education and 3 percent among those with at least secondary education). Childbearing decreases from 26 percent among adolescents in the lowest wealth quintile to just 2 percent among those in the highest wealth quintile. Poverty is quite plausibly an important consideration in understanding adolescent childbearing in Ghana (Nabila and Fayorsey, 1996). There has been no change in the overall percentage of teenage women who have begun childbearing over the last five years (GSS and MI, 1999).

FAMILY PLANNING

5

This chapter presents the 2003 GDHS findings on contraceptive knowledge and use, attitudes, and sources, as well as exposure to media messages about family planning. The information is particularly useful for policymakers, programme managers, and researchers in population and family planning, and provides a means to assess the success of the Ghanaian family planning programme. Although the focus is on women, some results from the male survey are also presented, since men play an important role in realising women's reproductive goals. Comparisons are also made, where feasible, with findings from previous surveys in order to evaluate trends occurring in Ghana over the last fifteen years.

5.1 KNOWLEDGE OF CONTRACEPTIVE METHODS

Acquiring knowledge about fertility control is an important step toward gaining access to and then using a suitable contraceptive method in a timely and effective manner. Information on knowledge of contraception was collected in two ways. Respondents were asked to mention all ways or methods couples can use to avoid or delay pregnancy. When a respondent failed to mention a particular method spontaneously, the interviewer described the method and asked whether the respondent knew of it. Using this approach, information was collected for 12 modern family planning methods: female and male sterilisation, the pill, the IUD, injectables, implants, male and female condoms, diaphragm, foam tablets and jelly, the lactational amenorrhoea method (LAM), and emergency contraception. Information was also collected on two traditional methods: rhythm or periodic abstinence, and withdrawal. Provision was also made in the questionnaire to record any other methods named spontaneously by respondents and this was coded as "folk methods." This report combines both prompted and unprompted knowledge. Thus, knowledge of a family planning method in the GDHS is defined simply as having heard of a method.

Tables 5.1.1 and 5.1.2 show the percentage of women age 15-49 and men age 15-59 who have heard of contraceptive methods among all women and men, currently married women and men, sexually active unmarried women and men, sexually inactive unmarried women and men, and for unmarried women and men with no sexual experience, by specific method.

The data show that knowledge of any contraceptive method is almost universal in Ghana, with 98 percent of all women and 99 percent of all men knowing at least one method of contraception. Modern methods are more widely known than traditional methods. Ninety-eight percent of all women know of a modern method compared with 75 percent who know of a traditional method. Among women, the male condom is the most commonly known (95 percent), followed by injectables (89 percent), the pill (88 percent), and the female condom (83 percent). Emergency contraception is the least known, reported by 28 percent of all women. Among the traditional methods, periodic abstinence is the most commonly known (65 percent), followed closely by withdrawal (61 percent), a small proportion (4 percent) mentioned folk methods.

Currently married women have a somewhat similar pattern of knowledge, especially with regard to level of knowledge. Among currently married women, 98 percent know at least one method of contraception or a modern method, and 78 percent know a traditional method. Among modern methods, the most commonly known method is the male condom (95 percent), followed by injectables (92 percent), the pill (90 percent), and the female condom (82 percent). Emergency contraception is the least known modern method (29 percent).

Table 5.1.1 Knowledge of contraceptive methods: women

Percentage of all women, of currently married women, of sexually active unmarried women, of sexu-
ally inactive unmarried women, and of women with no sexual experience who know any contracep-
tive method, by specific method, Ghana 2003

Number of women	5,691	3,549	257	1,002	884

[1] Had sexual intercourse in the month preceding the survey
[2] Did not have sexual intercourse in the month preceding the survey

Contraceptive knowledge is highest among sexually active unmarried women (almost 100 percent) and lowest among unmarried women who have never had sex (94 percent). Unmarried women reported the male condom to be the most commonly known method and are more likely to report knowledge of emergency contraception than LAM, regardless of their sexual activity status. Among the unmarried women who have never had sex, the female condom was the second most frequently mentioned method (80 percent) after the male condom (93 percent).

Knowledge of contraception is higher among men—99 percent know of at least one method of contraception (Table 5.1.2). Like women, a larger proportion of men (99 percent) know a modern method than a traditional method (80 percent). The most commonly known modern method is the male condom (98 percent). Similarly, periodic abstinence is the most commonly known traditional method (71 percent). It is worth noting that knowledge of implants and IUD is lower for men than for women.

Table 5.1.2 Knowledge of contraceptive methods: men

Percentage of all men, of currently married men, of sexually active unmarried men, of sexually inactive unmarried men, and of men with no sexual experience who know any contraceptive method, by specific method, Ghana 2003

Mean number of methods known	8.8	9.6	9.1	9.1	6.5
Number of men	5,015	2,671	485	707	1,154

[1] Had sexual intercourse in the month preceding the survey
[2] Did not have sexual intercourse in the month preceding the survey

Looking at the number of methods known, it is clear that knowledge of specific methods is lowest among both women and men who never had sex. For example, while married women have heard of an average of 8.9 methods and married men 9.6 methods, unmarried women and unmarried men who have never had sex report knowing only an average of 6.5 methods.

There has been an increase in levels of awareness of contraceptive methods over time. Among all women, the proportion who know any method has risen since 1988 for all methods (from 76 percent in 1988, 91 percent in 1993, 93 percent in 1998, to 98 percent in 2003), with the exception of knowledge of the diaphragm, which is no longer available in the country. The proportion who know of implants has risen steeply since 1993 (from 4 percent in 1993, 21 percent in 1998, to 62 percent in 2003). There is a similar trend for men. There are also remarkable increases in knowledge of IUD, male sterilisation, and LAM by men. The mean number of methods known has increased since 1998 from 5.8 to 8.6 for women and from 5.6 to 8.8 for men. This increase could be attributed partly to the fact that female condoms and injectables and training on emergency contraception were introduced into the national family planning programme in 2000.

5.2   EVER USE OF CONTRACEPTION

All women interviewed in the survey who said they had heard of a method of family planning were asked whether they had ever used that method. Men were asked if they had ever used "male-oriented" methods, i.e., male sterilisation, condoms, rhythm method, and withdrawal. Tables 5.2.1 and 5.2.2 show the percentages of women and men who have ever used family planning by specific method and age.

Forty-seven percent of all women report having used a method of contraception at some time, 39 percent have used a modern method, and 26 percent have used a traditional method. Of the modern methods, the male condom (18 percent) is the most commonly used method, followed by the pill (16 percent). Diaphragm and male sterilisation are the least used methods, with less than 1 percent reporting use of these methods. Of the traditional methods, periodic abstinence (19 percent) is the method most commonly used followed by withdrawal (14 percent). Emergency contraception has been used by 1 percent of all women.

Fifty-five percent of currently married women have used a method of contraception at some time, 45 percent have used a modern method, while 30 percent have used a traditional method. The pill is the most commonly used method (20 percent) followed by the male condom (17 percent) and injectables (13 percent). Use is particularly high among sexually active unmarried women, 73 percent of whom have used contraception. Sexually active unmarried women tend to use temporary methods of contraception rather than long-term or permanent methods. Forty-five percent of these women have used a male condom compared with only 17 percent of married women. Also, compared with currently married women, ever use of emergency contraception, the pill and the female condom is higher among sexually active unmarried women.

Table 5.2.2 shows the percentage of all men, currently married men and sexually active unmarried men who reported having ever used one of four male methods of contraception—male sterilisation, male condom, periodic abstinence or withdrawal. The most popular male method, the condom, has been used by 39 percent of all men, 47 percent of currently married men, and 70 percent of sexually active unmarried men. Male sterilisation is practically non-existent in Ghana. Of the two traditional methods, periodic abstinence is reported as used more often than withdrawal by all men (30 percent) and currently married men (43 percent) but is less popular than withdrawal among sexually active unmarried men (36 percent).

Table 5.2.1 Ever use of contraception: women

Percentage of all women, of currently married women, and of sexually active unmarried women who have ever used any contraceptive method, by specific method and age, Ghana 2003

5.3   CURRENT USE OF CONTRACEPTIVE METHODS

The level of current use of contraceptive methods is one of the indicators most frequently used to assess the success of family planning programme activities. It is also widely used as a measure in analysing the determinants of fertility. This section focuses on the levels and differentials in current use of family planning.

Table 5.3 shows the percent distribution of women who are currently using specific family planning methods by age. One in five women is currently using any contraceptive method. The use of any contraceptive method increases with age, reaching its peak at age group 30-34 (28 percent), and then starts to decline. Modern methods are used by 15 percent of women, while only 5 percent are using traditional methods. Male condoms, pills, and injectables are the most commonly used methods (4 percent each). Female sterilisation, implants, and IUD are used by roughly 1 percent each, while female

condoms, foam/jelly, and diaphragms[1] are the least used modern methods (less than 1 percent each). Of the traditional methods, periodic abstinence is the most commonly used (4 percent), while withdrawal is used by 1 percent. Less than 1 percent use folk methods.

The contraceptive prevalence rate among currently married women is 25 percent. Among currently married women, the pill (6 percent) is the most commonly used modern method, followed closely by injectables (5 percent). Male condoms and female sterilisation are used by 3 percent and 2 percent of currently married women, respectively, while implants and IUD are used by 1 percent each. The most commonly used traditional method is periodic abstinence, used by 5 percent of currently married women. After the male condom (18 percent), the most commonly used modern method among sexually active unmarried women is the pill (8 percent), while periodic abstinence (9 percent) is the most widely used traditional method. Sexually active unmarried women are nearly twice as likely to report use of both any modern and any traditional method than currently married women. The difference may be due to the greater use of male condoms by sexually active unmarried women. This group is six times as likely to use male condoms as currently married women.

Table 5.4 and Figure 5.1 show the percent distribution of currently married women by current use of family planning methods, according to background characteristics. Current use of contraception varies

LAM = Lactational amenorrhoea method

Figure 5.1
Current Use of Family Planning Among
Currently Married Women Age 15-49

with urban-rural and regional residence, education level, and number of living children. Women in urban areas are more likely to use contraceptive methods (31 percent) than their rural counterparts (21 percent). Male condoms, IUD, and female sterilisation use in urban areas is two to three times higher than in rural Ghana. The more urbanised regions such as Greater Accra, Brong-Ahafo, and Ashanti, have contraceptive prevalence rates of 30-34 percent. Two of the three northern regions (Upper East and Northern) and Central Region report the lowest levels of contraceptive use (12 percent each in the Northern and Upper East regions, and 15 percent in the Central Region). Women with at least some secondary education are more than twice as likely to use contraception as women with no education. Use of female sterilisation, implants, male condoms, IUD, LAM, and periodic abstinence all increase with education.

The proportion currently using contraception generally increases with increasing number of children. Fourteen percent of women without children are currently using contraceptive methods, compared with 26 percent of women with five or more children. Current use of contraception is, however, highest among women who have three or four children (31 percent). Use of female sterilisation, implants, and LAM increases with increasing number of children.

Wealth and current use of contraception is positively related, increasing from 14 percent among currently married women in the lowest quintile to 35 percent in the highest quintile. The gap in use is especially large between women in the lowest wealth quintile and all other wealth quintiles, and is obvious for all methods with the exception of female sterilisation, which shows an isotonic increase from lowest to highest wealth quintile.

The pattern of current use of modern and traditional methods of contraception is generally similar across subgroups. Use of both modern and traditional methods are more common in urban than rural areas, increases with increasing education and wealth quintile.

5.4   TRENDS IN THE USE OF FAMILY PLANNING

Table 5.5 and Figure 5.2 show the trend in the use of family planning among currently married women based on data from the 1988, 1993, 1998, and 2003 GDHS surveys.

Figure 5.2
**Trends in Current Use of Contraceptive Methods
Ghana, 1988-2003**

GDHS 1988-2003

The current use of contraception among currently married women shows an increase from 13 percent in 1988, 20 percent in 1993, 22 percent in 1998, to 25 percent in 2003. There has been a steady increase in the use of modern methods from 5 percent in 1988, 10 percent in 1993, 13 percent in 1998 to 19 percent in 2003. However, while there was an increase in the use of traditional methods from 8 percent in 1988 to 10 percent in 1993, use of these methods have since decreased to 9 percent in 1998 and 7 percent in 2003. Use of male condoms, pills, injectables, and implants have increased markedly. For example, pill use more than doubled, use of injectables increased from less than 1 percent to 5 percent, and male condom use increased from less than 1 percent to 3 percent, between 1988 and 2003. A major IEC campaign called *Life Choices,* which aimed at repositioning family planning (from being a purely clinical or health issue to being a choice one makes in life according to personal reproductive goals), may have contributed significantly to the increased use of modern methods.

5.5   CURRENT USE OF CONTRACEPTION BY WOMEN'S STATUS

Women's status plays a very important role in access to and use of family planning services as well as other reproductive and child health services and is a determinant of contraceptive use. Table 5.6 presents the distribution of currently married women by contraceptive method currently used, according to selected indicators of women's status.

A woman's desire and ability to manage her fertility and her choice of contraceptive methods are in part affected by her status, self-image, and sense of empowerment. A woman who feels that she does not have much control over basic aspects of her life may be less likely to feel she can make and carry out decisions about her fertility. She may also feel the need to choose methods that are less obvious or that do not depend on her husband's cooperation.

There does not appear to be a clear relationship between the three measures of women's status and current contraceptive use among currently married women. Nevertheless, women who believe that wife-beating is not justified for any reason at all seem to be slightly more likely to use contraceptives than other women.

Table 5.6 Current use of contraception by women's status

Percent distribution of currently married women by contraceptive method currently used, according to indicators of women's status, Ghana 2003

Women's status indicator	Any method	Any modern method	Modern method										Any traditional method	Traditional method			Not currently using	Total	Number of women

Note: If more than one method is used, only the most effective method is considered in this tabulation.
 LAM = Lactational amenorrhoea method
[1] Either by herself or jointly with others

5.6 NUMBER OF CHILDREN AT FIRST USE OF CONTRACEPTION

The decision to initiate family planning use differs according to the circumstances of couples and individuals concerned. Contraceptive methods may be used for limiting births when they have already had the desired number of children (i.e., to stop having children), or spacing births (i.e., to delay the interval between births), or postpone a first birth. In the 2003 GDHS, women were asked how many children they had at the time they first used a method of family planning. The number of living children at the time of first use of contraception is a measure of willingness to postpone the first birth and of a deliberate effort at spacing births. Thus, differences in fertility-controlling behaviour of different cohorts of women can be observed by examining the number of living children at first use of contraceptives by age of the woman.

Table 5.7 shows the percent distribution of women who have ever used contraception by number of living children at the time of first use of contraception, according to current age. Two in five women age 15-49 years report first use of contraception before the birth of their first child. Younger women (age 15-34) reported first use of contraceptives at lower parities than older women. Among older women, those who ever used contraception tended to start only when they had at least four children. In contrast, younger users tend to start when they had only one child or none. For example, 93 percent of women 15-19 who have used contraception started before they had any children, compared with 12 percent of women age 45-49. In a culture where smaller family size is becoming a norm, young women adopt family planning at an earlier age than their older counterparts. The data suggests a move towards the early use of contraceptives among younger Ghanaian women to delay childbearing. On the other hand, older women initiate contraceptive use at a later age primarily to limit rather than space births.

Table 5.7 Number of children at first use of contraception

Percent distribution of women who have ever used contraception by number of living children at the time of first use of contraception, according to current age, Ghana 2003

Current age	Number of living children at time of first use of contraception						Total	Number of women

5.7 USE OF SOCIAL MARKETING BRANDS

It is important for programme purposes to get a sense of whether the social marketing of contraceptives is successful. Questions on social marketing in Ghana were restricted to the use of the pill and condom, since they are the most commonly used modern methods of contraception. Pill and condom users were asked for the brand name and the cost.

Secure is the brand of oral contraceptive pill that is socially marketed by the Ghana Social Marketing Foundation (GSMF). Ovrette, Microgynon, Micronor, and Lo-femenal are brands provided by the public sector and at the Planned Parenthood Association of Ghana (PPAG) clinics. The other brands

are mainly sold in the private commercial sector. Table 5.8 shows that the brand marketed by GSMF is by far the most popular brand of pill used in Ghana. One in two women use *Secure*, compared with one in eight women using brands marketed by the public sector. The most common, Lo-femenal, is used by 8 percent of pill users. One in six women use brands marketed by the private sector—the most common, Duofem, is used by 7 percent of pill users. Table 5.8 also shows the average cost of a cycle of pills by brand name for women who know the cost. The average cost of a cycle of pills is 1,366 cedis[2] irrespective of the brand, but cost varies markedly by the brand type, ranging from a high of 1,667 cedis for Micronor to a low of 935 cedis for Ovrette.

Table 5.8 Pill brand and cost		
Percent distribution of pill users and average cost per cycle, by brand of pill according to source, Ghana 2003		
Brand by source	Users	Cost per cycle (cedis[1])
GSMF		
Secure	50.3	1,087
Public		
Ovrette	3.1	935
Microgynon	0.8	1,000

Total	100.0	na
Number	235	216

[1]One US$ is equivalent to 8,992 cedis. Excludes users who don't know cost.
GSMF = Ghana Social Marketing Foundation
na=Not applicable

As seen in Table 5.9, GSMF plays an important role in the marketing of condoms too. Sixty-three percent of men who report use of condom mention using brands marketed by GSMF (Protector, Champion, and Panther), 16 percent use a privately marketed brand (Rough Rider or other), and 4 percent used a brand marketed by the public sector (no brand name/no logo). Table 5.9 also shows the average cost of condoms by brand name among men who knew the cost of condoms. The most popular condom, Champion, is also the cheapest. Condoms marketed by the private sector are much more expensive than those marketed by GSMF or the public sector.

---

[2] One US$ is equivalent to 8,992 cedis.

Table 5.9 Condom brand and cost

Percent distribution of condom users and average cost per condom by brand of condom according to source, Ghana 2003

Brand name	Users	Cost per condom (cedis[1])
GSMF

Total	100.0	na
Number	1,981	1,838

[1]One US$ is equivalent to 8,992 cedis. Excludes users who don't know cost.
GSMF = Ghana Social Marketing Foundation
na=Not applicable

The market share of socially marketed pills and condoms has increased in the last five years. GSMF brands of pills and condoms increased by 35 percent and 27 percent, respectively, in the five years between 1998 and 2003. In 1998, pills marketed by GSMF accounted for 37 percent of current users, while condoms sold by GSMF accounted for 50 percent of current users (GSS and MI, 1999).

5.8   KNOWLEDGE OF FERTILE PERIOD

A basic knowledge of reproductive physiology is especially useful for the successful practice of coitus-related methods such as withdrawal, condom, vaginal methods, and other fertility-awareness-based methods collectively called periodic abstinence. Knowledge of the fertile period is particularly critical in the case of periodic abstinence. The successful practice of natural family planning depends on an understanding of when during the menstrual cycle a woman is most likely to conceive.

All women and men in the 2003 GDHS were asked about their knowledge of a woman's fertile period. The results are presented in Table 5.10 for users and non-users of periodic abstinence. Only about three-tenths of all women and all men (29 and 28 percent, respectively) reported correct knowledge of a woman's fertile period, that is, that a woman is most likely to conceive half way between two periods. Users of natural family planning methods are more knowledgeable about their ovulatory cycle; 62 percent of female users of natural family planning correctly identified the middle of the cycle as the fertile time compared with 28 percent of non-users of the method. Knowledge of the fertile period among men was lower than for women. Forty-five percent of male users of natural family planning correctly identified the middle of the cycle as the fertile time, compared with 27 percent of non-users of the method. One-third of women wrongly reported that the fertile period occurs right after a woman's period has ended, with 30 percent of users of periodic abstinence reporting so. Nineteen percent reported not having any knowledge of the fertile period. This is an improvement over the results of the 1993 GDHS,

where nearly half of all women did not have correct knowledge of the fertile period. In that survey, 28 percent of all women and 55 percent of users of periodic abstinence correctly knew of the fertile period, while 20 percent of all women reported that the fertile period is right after the period has ended. Comparable data were not available for the 1998 GDHS.

Table 5.10 Knowledge of fertile period

Percent distribution of women and men by knowledge of the fertile period during the ovulatory cycle, according to current use/non-use of periodic abstinence, Ghana 2003

Perceived fertile period	Women			Men

Number of respondents	238	5,453	5,691	261	4,754	5,015

5.9   SOURCE OF SUPPLY

Information on sources of modern contraception is important to family planning programme management. In Ghana, both public and private sectors are strategically important in the provision of family planning services. Non-clinical short-term methods such as the pill and condoms are widely distributed by the private sector. Ghana has a vibrant social marketing programme that networks with pharmacies and chemical sellers, private clinics and maternity homes as well as major NGOs, such as the PPAG, which provide both clinical and non-clinical methods. The public sector provides the full range of clinical and non-clinical methods mainly through health facilities and also supports major partners such as PPAG.

In the 2003 GDHS, all current users of modern contraceptive methods were asked the most recent source of their methods. Interviewers were instructed to record the name of the source or facility, because respondents may not always be able to accurately categorise a source as public or private. Supervisors and editors then verified this information. This procedure helped in improving the accuracy of the information.

The results are shown in Table 5.11 and Figure 5.3 and indicate that in Ghana both the public and private sectors are important sources of supply for users of modern methods (41 and 54 percent, respectively). The most common public sector sources are government hospitals and polyclinics, which provide most of the services (26 percent), while government health centres and family planning clinics provide 11 and 4 percent, respectively. Within the private sector, pharmacies, chemists, and drug stores are the largest source, supplying 43 percent of all current users. Seven percent of users also mentioned private hospitals or clinics and 3 percent mentioned maternity homes and PPAG clinics. Other sources such as family, relatives, and shops are the least common (2 percent).

Table 5.11 Source of contraception

Percent distribution of current users of modern contraceptive methods by most recent source of method, according to specific method, Ghana 2003

Source	Female sterilisation	Pill	IUD	Inject-ables	Implants	Male condom	Total

Missing	1.8	0.0	(0.0)	0.0	(0.0)	3.5	1.2
Total	100.0	100.0	(100.0)	100.0	(100.0)	100.0	100.0
Number of women	72	235	35	208	37	246	858

Note: Table excludes lactational amenorrhoea method (LAM). Figures in parentheses are based on 25-49 unweighted cases. Total includes 7 users of female condom, 3 users of the diaphragm and 12 users of foam/jelly.
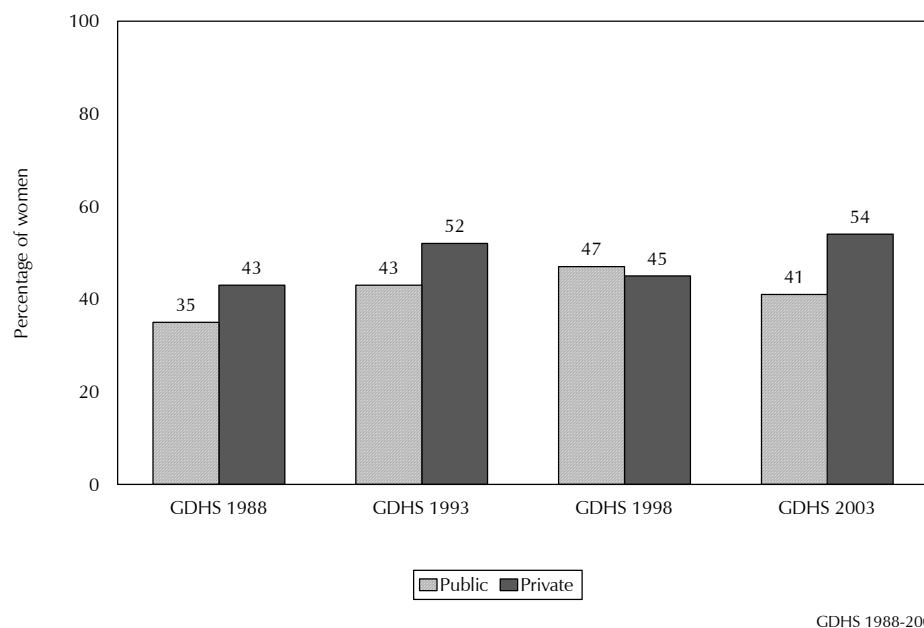

In the last fifteen years, there has been a shift in the source of modern contraceptive methods from the public to the private sector (Figure 5.3). The proportion of current users relying on private medical sources has increased from 43 percent in 1988 to 52 percent in 1993, declined to 45 percent in 1998 and then increased to 54 percent in 2003. Reliance on public sources for all modern methods increased from 35 percent in 1988, 43 percent in 1993, to 47 percent in 1998, with a decline (41 percent) in 2003.

There are differences by method among the sectors. Male condoms and pills are commonly obtained from private sources (82 and 77 percent, respectively), while clinic-based methods such as IUD, injectables, and implants are provided predominantly by public facilities. Female sterilisation requires medical personnel and is available mostly in public sector hospitals (69 percent) and some private hospitals and clinics (29 percent).

5.10   INFORMED CHOICE

Informed choice is an important aspect of the delivery of family planning services. Family planning providers should inform all method users of potential side effects, what they should do if they

Figure 5.3 Trends in Source of Modern Contraceptive
Methods, Ghana 1988-2003

GDHS 1988-2003

encounter signs of a problem, and alternate options. This information assists users in coping with side effects and decreases unnecessary discontinuation of temporary methods.

Table 5.12 shows that about half of family planning clients receive relevant information to make informed choices. Health providers are somewhat more likely to inform users of modern methods about side effects or problems of method used (54 percent) and about what other methods could be used (53 percent) than about what to do if they experienced side effects (50 percent). Information varies by type of method, being least likely to be provided to users of female sterilization (24 percent).

Public sector clients received more information than private sector clients (seven and four in ten, respectively). Pharmacy, chemist, and drug store clients received the least information (three in ten). Slightly higher proportions of urban residents received relevant information than their rural counterparts, particularly with respect to information on other methods that could be used (59 and 48 percent, respectively). Most of the regional information is based on small numbers of users. There appears to be no major differentials in informed choice by educational level. Among wealth quintiles the least informed are women in the middle quintile with the women from the highest quintile receiving the most information.

Table 5.12 Informed choice

Among current users of modern contraceptive methods who adopted the current method in the five years preceding the survey, percentage who were informed about the side effects of the method used, percentage who were informed what to do if side effects were experienced, and percentage who were informed of other methods that could be used for contraception, by specific method, initial source of method, and background characteristics, Ghana 2003

5.11   FUTURE USE OF CONTRACEPTION

Intention to use family planning is an important indicator of the potential demand for services. Currently married women who were not using contraceptives at the time of the survey were asked about their intention to use family planning in the future. The results are shown in Table 5.13. The table reveals that of the currently married female non-users, 54 percent intend to use a method of contraception in the future, while 42 percent have no intention to use any method. Four percent are not sure of their contraceptive use intention.

Table 5.13 Future use of contraception

Percent distribution of currently married women who are not using a contraceptive method by intention to use in the future, according to number of living children, Ghana 2003

Intention	Number of living children[1]					Total
	0	1	2	3	4+	
Intends to use	56.6	59.3	54.9	58.2	49.0	54.1
Unsure	5.2	4.6	4.8	5.5	2.8	4.1
Does not intend to use	38.2	36.0	39.7	35.8	48.1	41.5
Missing	0.0	0.2	0.6	0.5	0.2	0.3
Total	100.0	100.0	100.0	100.0	100.0	100.0
Number of women	190	491	488	451	1,035	2,655

[1] Includes current pregnancy

There has been an increase in the percentage of currently married non-users who intend to use family planning in the future (including those who intend to use but are not sure of timing), from 37 percent in 1988, to 51 percent in 1993, followed by a slight decline to 48 percent in 1998, and then an increase to 58 percent in 2003.

5.12   REASONS FOR NOT INTENDING TO USE CONTRACEPTION

Table 5.14 presents the main reasons for not intending to use contraception given by currently married women age 15-29 and 30-49 years who do not intend to use a contraceptive method in the future.

The main reasons for not intending to use any contraception in the future among currently married women are fertility-related issues (41 percent), followed by method-related reasons (37 percent). Among fertility-related reasons, 17 percent of younger women state that they want as many children as possible, while older women (20 percent) do not intend to use because they are subfecund or infecund.

Fear of side effects was the most cited method-related reason for non-use among all women (26 percent). This reason is particularly cited by younger women (34 percent) than women 30 years and older (23 percent). This calls for a continued intensification of information and counseling on side effects of contraceptive methods by the family planning programme in Ghana. Younger women are also more likely to be opposed to family planning than older women (9 and 5 percent, respectively). Fear of side effects has increased in importance as a reason for non-use since 1998, from 18 to 26 percent.

Table 5.14 Reason for not intending to use contraception

Percent distribution of currently married women who are not using a contraceptive method and who do not intend to use in the future by main reason for not intending to use, according to age, Ghana 2003

Reason	Age		Total
	15-29	30-49

5.13 PREFERRED METHOD OF CONTRACEPTION FOR FUTURE USE

Asking non-users who say they intend to use a family planning method in the future for the type of method they would prefer to use is a way to assess the potential demand for specific methods of family planning.

Table 5.15 shows that among currently married women, the contraceptive method most commonly preferred for future use is injectables (43 percent), followed by the pill (15 percent) and implants (11 percent). There has been a slight change in the order of preferred methods by currently married women since the 1998 GDHS. The proportion of non-users preferring the injectable increased from 36 percent in 1998 to 43 percent in 2003, while the proportion of non-users who prefer to use the pill has decreased from 21 percent in 1998 to 15 percent in 2003. Preference for implants increased from 4 percent in 1998 to 11 percent in 2003. Intention to use the IUD also increased from 2 percent in 1998 to 4 percent in 2003 and is the same among both younger and older women. Older respondents are more likely to intend to use permanent methods than younger ones. For example, among respondents in the age group 30-49, 5 percent say they would prefer female sterilisation compared with 2 percent among those in the age group 15-29.

Table 5.15 Preferred method of contraception for future use

Percent distribution of currently married women who are not using a contraceptive method but who intend to use in the future by preferred method, according to age, Ghana 2003

Method	Age		Total

Number of women	748	689	1,437

5.14   EXPOSURE TO FAMILY PLANNING MESSAGES

The media is seen as an effective means to disseminate family planning information. To assess the extent to which media serve as sources of family planning messages, respondents were asked whether they had heard or seen a message about family planning on the radio, television, newspapers or magazines, posters, leaflets or brochures, from health workers, and community meetings in the few months preceding the survey. The results are shown in Table 5.16.1 for women and Table 5.16.2 for men and in Figure 5.4.

Radio is the most frequent source of family planning messages for both women (77 percent) and men (86 percent). Fifty-two percent of women and 58 percent of men saw a family planning message on the television in the few months preceding the survey. About half of women and men are also exposed to family planning messages through posters. Health workers are also mentioned as an important source by 47 percent of women and 44 percent of men, while 34 percent of women and 36 percent of men mentioned hearing about family planning at community meetings. Newspapers and magazines are the least common source of family planning messages for both women (20 percent) and men (33 percent). About one in five women and one in nine men were not exposed to a family planning message through the radio, television, or newspaper/magazine in the few months prior to the survey. Thirteen percent of women and 9 percent of men have had no exposure to family planning messages from any media source.

Exposure to family planning messages is more common among men than women and in urban than rural areas, and increases with increasing level of education and wealth quintile. Among the regions, women in the Upper East, Brong-Ahafo, Eastern, and Ashanti regions and men in the Western, Central and Greater Accra regions have by far the highest exposure to family planning messages through any media, while respondents in the Upper West and Northern regions have the lowest.

Table 5.16.1 Exposure to family planning messages: women

Percentage of women who heard or saw a family planning message on various media sources in the past few months, according to background characteristics, Ghana 2003

GDHS 2003

5.15   EXPOSURE TO SPECIFIC RADIO MESSAGES ON FAMILY PLANNING

The 2003 GDHS survey collected information from women and men about whether they had heard specific radio adverts and slogans on family planning from the *Life Choices* campaign in the few months before the survey. The slogans included the following: *Life Choices: It's your life, it's your choice; Make the choice that is best for you; Contraceptives are safe and effective;* and *Obra ni wora bo*[3]. Table 5.17 shows the percentages of women and men who have heard the specific radio messages and slogans of Life Choices in the few months preceding the survey, by background characteristics.

Of the four slogans asked about, the most common is *Obra ni wora bo*, heard by 68 percent of women and 75 percent of men. The remaining messages were heard in the following order: *Life Choices: It's your life. It's your choice*, *"Make the choice that is best for you"* with *"Contraceptives are safe and effective"* being the least heard message, by both sexes. Men are more likely than women to have heard each of the messages.

The percentage of women and men who have been exposed to specific radio messages generally decreases with age, is higher among urban residents than rural residents, and increases with increasing level of education and wealth. Never-married women and, in some cases, men are more likely to have heard specific slogans on family planning than those currently in union or formerly married.

The national-level campaign was launched in Greater Accra in 2001, followed by the regional campaigns. Exposure to the first three specific radio messages is highest in Greater Accra, while exposure to *Obra ni wora bo* is highest in the Ashanti Region and in the other predominantly Akan-speaking regions. Exposure to family planning messages and specifically these four messages is particularly low in the three northern regions.

---

[3] *Obra ni wora bo* is an Akan phrase that translates to "Life is what you make of it." In terms of the Life Choices campaign, therefore, it implies "Your (reproductive) life depends on the choices you make."

5.16 CONTACT OF NON-USERS WITH FAMILY PLANNING PROVIDERS

In the 2003 GDHS, women who were not using contraception were asked whether they had attended a health facility in the last year for any reason and, if so, whether a staff person at that facility spoke to them about family planning methods. This information is important for determining whether non-users of family planning in Ghana have had an opportunity to receive information about family planning from providers.

Table 5.18 shows that 15 percent of non-users reported that they had visited a health facility and discussed family planning, while 11 percent of women were visited by a fieldworker who discussed

Table 5.18 Contact of non-users with family planning providers

Percentage of women who are not using contraception who were visited by a fieldworker who discussed family planning, who visited a health facility and discussed family planning, and who visited a health facility but did not discuss family planning, in the 12 months preceding the survey, by background characteristics, Ghana 2003

Highest	7.0	13.2	36.0	82.2	1,099
Total	10.8	14.7	26.9	78.6	4,514

family planning in the 12 months preceding the survey. Roughly one in four women (27 percent) visited a health facility but did not discuss family planning. The majority of the women did not discuss family planning with a fieldworker or at a health facility.

Women age 20-44 are more likely to have discussed family planning at a health facility than women age 15-19 and 45-49.

Urban women are less likely to have discussed family planning with health staff than rural women, as are highly educated women compared with women with no education, and women in the highest wealth quintile as compared with women in the lowest wealth quintile. It could be that these groups are already using the methods or already have information and therefore do not feel the need to discuss family planning with providers or are less likely to have visited a facility. Discussion of family planning with staff at health facilities or in the field is highest in the Volta region (29 and 24 percent, respectively) and lowest in the Central region (8 and 5 percent, respectively).

5.17 DISCUSSION ABOUT FAMILY PLANNING WITH HUSBAND

Although discussion of family planning between husband and wife is not a precondition for adoption of contraception, its absence may be an impediment to use. Inter-spousal communication is thus an important intermediate step along the path to eventual adoption and especially continuation of contraceptive use. Lack of discussion may reflect a lack of personal interest, hostility to the subject, or customary reticence in talking about sex-related matters. To explore this subject, women interviewed in the 2003 GDHS were asked the number of times they discussed family planning with their husband in the 12 months preceding the survey.

Table 5.19 provides information for currently married women who know of at least one contraceptive method about the number of times family planning was discussed with their husbands in the past year, according to age. The data indicate that 37 percent of women reported having discussed family planning with their husbands once or twice, and 21 percent discussed family planning with their husbands at least three times. About two in five (41 percent) never discussed family planning with their husbands in the past year. Women age 25-29 are the most likely to report frequent discussions (three or more times) with their husbands (25 percent), while women 15-19 are least likely (9 percent).

Table 5.19 Discussion of family planning with husband

Percent distribution of currently married women who know a contraceptive method by the number of times they discussed family planning with their husband in the past year, according to current age, Ghana 2003

| Age | Number of times family planning was discussed with husband | | | | Total | Number of women |
	Never	One or two	Three or more	Missing		
15-19	59.8	30.7	8.8	0.7	100.0	133
20-24	39.8	39.0	20.7	0.6	100.0	517
25-29	33.9	40.4	24.9	0.8	100.0	724
30-34	36.6	38.8	24.1	0.5	100.0	657
35-39	40.0	37.4	21.6	1.0	100.0	614
40-44	44.3	37.5	17.1	1.1	100.0	466
45-49	55.9	29.2	14.6	0.3	100.0	367
Total	41.1	37.4	20.8	0.7	100.0	3,479

The results indicate that there has been an increase over the past ten years in the proportion of couples who discuss family planning. The proportion of couples who discussed family planning at least once has increased steadily from 42 percent in 1988, 46 percent in 1993, 54 percent in 1998, to 58 percent in 2003.

5.18 ATTITUDES OF MEN TOWARDS FAMILY PLANNING

The 2003 GDHS included questions in the male survey to illicit information on men's attitudes towards contraception in general. This information is useful in formulating family planning programmes and policies because men play a key role in their own as well as in women's reproductive health and behaviour. This information is useful in formulating educational activities geared towards addressing some misconceptions and fears. It will be useful in the future to examine men's attitude towards male methods.

To get a sense of their attitudes toward contraception in general, men were asked their opinion on a number of questions pertaining to contraception and its use. The questions addressed whether men perceived contraception to be a woman's business, whether women who use contraception may become promiscuous, and whether a woman should be sterilised because she is the one who gets pregnant. Table 5.20 presents the results by background characteristics. About one in three men (35 percent) consider contraception to be a woman's business, while roughly half of the men (53 percent) feel that women who use contraception may become promiscuous, and 41 percent of men feel that a woman should get sterilised since she is the one who becomes pregnant.

There is no uniform pattern in men's attitudes about family planning by background characteristics. However, some general comments can be made. Men in the youngest cohort (15-19), never-married men, men in the Volta re-

Table 5.20 Men's attitudes towards contraception

Total	35.0	53.0	40.9	4,960

Note: Figures in parentheses are based on 25-49 unweighted cases.

gion, men with secondary education and higher, and men in the highest wealth quintile are generally less likely to have negative attitudes about family planning than other men. The results indicate a larger scope for dissemination of family planning messages to improve men's attitude towards family planning.

5.19   ATTITUDES OF COUPLES TOWARDS FAMILY PLANNING

When couples have a positive attitude towards family planning, they are more likely to adopt a family planning method. In the 2003 GDHS, married women were asked whether they approved of couples using family planning and what they perceived as their husband's attitude towards family planning. Men were also asked whether they approved of couples using family planning. This information is important in the formulation of family planning policies because it indicates the extent to which further education and publicity are needed to increase acceptance of family planning.

Tables 5.21.1 and 5.21.2 show the percent distribution of currently married women and men who know a contraceptive method, by approval of family planning, according to background characteristics. An overwhelming majority of married women and men (87 and 89 percent, respectively) approve of family planning. Eleven percent of women and 10 percent of men disapprove of couples using family planning, while 2 percent each of women and men are unsure about their attitude towards use of family planning by couples. Approval of family planning among respondents is higher in urban than rural areas and increases with increasing level of education and wealth.

Table 5.21.1 also shows women's perception of their husband's attitude towards family planning, Two-thirds of married women who approve of family planning believe that their husband also approves. Women in the youngest cohort, rural women, women from the Northern region, women with no education, and women in the poorest wealth quintile are more likely than other women to not know their husbands' attitudes towards family planning.

From data gathered in the 2003 GDHS survey, information on attitude towards family planning can be tabulated for the 1,949 couples. Table 5.22 shows the percent distribution of couples by husband's actual attitude towards family planning according to wife's perception of husband's attitude and is a

measure of the percentage of couples with discordant attitudes towards family planning and of the extent of knowledge of each other's attitude.

The data indicate that wives are generally accurate when they report on their husband's approval of family planning. Wives' perceptions of their husbands' approval of family planning is consistent with husbands' actual attitudes in the majority of cases (88 percent). However, in 78 percent of cases when the wife reported that her husband disapproved of family planning, the opposite was true and the husband actually approved. At the same time, in 8 percent of cases the wife perceived that her husband approved of family planning when he actually disapproved. This information reinforces the importance of spousal communication and shows that there is a potential for the Ghanaian family planning programme to benefit from greater male involvement.

Table 5.22 Wife's perception of husband's attitude toward family planning

Note: Figures in parentheses are based on 25-49 unweighted cases.

OTHER PROXIMATE DETERMINANTS OF FERTILITY   6

This chapter addresses the principal factors, other than contraception, which affect a woman's risk of becoming pregnant. These factors include marriage, polygyny, sexual intercourse, postpartum amenorrhoea, abstinence from sexual relations, and termination of exposure to pregnancy. Direct measures of the onset of exposure to the risk of pregnancy and the level of exposure are also discussed in this chapter.

6.1   CURRENT MARITAL STATUS

Table 6.1 shows data on the current marital status of women and men interviewed in the 2003 GDHS. In this report, the term "currently married" refers to both women in a formal union and women in an informal union. Marriage and cohabitation are generally considered to be primary indicators of exposure to the risk of pregnancy. In Ghana, however, a union is not a prerequisite to childbearing as some childbearing occurs outside union.

Table 6.1 shows that 28 percent of women age 15-49 have never married, 54 percent are formally married, 8 percent are living together, and 9 percent are divorced, separated, or widowed. Marriage occurs relatively early in Ghana, and two in every five women age 20-24 are currently married. Less than 1 percent of women age 40 and over have never married. The proportion separated is highest among women age 30-34. The proportion divorced or widowed generally increases with age.

Table 6.1 Current marital status

Percent distribution of women and men by current marital status, according to age, Ghana 2003

Total	40.7	48.6	4.6	2.0	3.4	0.6	100.0	5,015

A greater proportion of men (41 percent) than women (28 percent) have never married. Almost half of men (49 percent) are married, 5 percent are living together, and another 6 percent are divorced, separated, or widowed. Men tend to marry at older ages than women. While two in three women age 25-29 are married, the proportion of men married in the same age group is two in five.

Data from earlier DHS surveys show that there has been a noticeable increase in the proportion of women and men never married. Twenty percent of women age 15-49 were never married in 1993 (GSS and MI, 1994) and 24 percent in 1998 (GSS and MI, 1999) compared with 28 percent in 2003. Even more impressive is the marked increase in the percentage of women never-married in the cohort age 20-24, from 29 percent in 1998 to 42 percent in 2003. The proportion of never-married men age 15-59 increased only between 1993 and 1998, with little difference between 1998 and 2003. The proportion divorced has decreased for women over the past five years, from 5 percent in 1998 (GSS and MI, 1999) to 3 percent in 2003, while the proportion separated decreased from 5 percent in 1998 to 4 percent in 2003.

6.2 POLYGYNY

Polygyny (the practice of having more than one wife at the same time) has implications for the frequency of sexual activity and fertility. Married women were asked whether their husbands had other wives and, if so, how many. Married men were asked whether they had one or more wives or partners.

Table 6.2 shows that 23 percent of married women in Ghana are in polygynous unions compared with 13 percent of men. Ten percent of women say they have one co-wife, while 13 percent say they have two or more co-wives. Married men are less likely to report having multiple wives. This discrepancy between the number of wives and co-wives reported by men and women may be due to definitional or conceptual problems of who is a wife. By definition, it is higher among women than men because if a man has two wives, both have co-wives, while he is only one man reporting more than one wife. Conceptual differences may arise because of the tendency for women to describe their husband's mistresses or girlfriends as wives, whereas men are less likely to classify girlfriends as wives.

The level of polygyny increases with age for both women and men. Rural women and men are more likely to be in polygynous unions than their urban counterparts. Regional variations are also noticeable. Women and men in the Northern, Upper East, and Upper West regions are more likely to report being in a polygynous union than those in other regions (Figure 6.1). Married women in Greater Accra (13 percent) and married men in the Ashanti Region (7 percent) are least likely to be in a polygynous union.

There is an inverse relationship between respondent's education and polygyny. Thirty-six percent of women with no education are in a polygynous union compared with 9 percent of women with secondary and higher education. The corresponding data for men are 28 percent and 7 percent, respectively.

The level of polygyny among women has decreased from 28 percent in 1993 (GSS and MI, 1994) to 23 percent in both 1998 and 2003. Comparable information for men is not available for 1993, but data for 1998 (13 percent) show that there has been no change in the percentage of men who report being in a polygynous relationship over the last five years.

Figure 6.1 Percentage of Married Men with Two or More Wives, by Region

GDHS 2003

6.3   AGE AT FIRST MARRIAGE

Marriage marks the point in a woman's life at which childbearing becomes socially acceptable in Ghana. Marriage is, therefore, closely associated with fertility because women who marry early will, on average, have a longer exposure to the probability of becoming pregnant. Early age at first marriage is an important fertility indicator because it not only affects the length of time a woman is exposed to the risk of pregnancy, but also tends to lead to early childbearing and to higher fertility. Information on age at first marriage was obtained by asking respondents the month and year, or age, at which they started living with their first partner. Older respondents are less likely to recall with accuracy marriage dates and ages, therefore, the data for older respondents should be interpreted with caution.

Table 6.3 shows that the median age at marriage among women age 20-49 is 19.6, a slight increase over the past five years from 19.1 years. There is a general trend towards later marriage. More than one-third of women (35 percent) age 25-49 are married by exact age 18 compared with 38 percent of women in the same age group five years ago (GSS and MI, 1999). By age 20, more than half (56 percent) of women age 25-49 were married and by age 25 the proportion married among the same age group is 85 percent. It is to be noted that the median age at first marriage for women age 25-49 is 19.4 years and is only slightly lower (0.5 years) among women age 45-49 years than among those age 25-29 years.

Table 6.3 also provides information about age at first marriage among men. Men tend to marry at a later age than women. For example, the median age at first marriage for those age 30-34 years is 25.0 years compared with 19.1 years for women in the same age group. About half of men are married by age 25 compared with more than four in five (85 percent) women.

30-59	14.9	28.4	52.2	71.5	80.5	5.3	2,470	24.7

Note: The age at first marriage is defined as the age at which the respondent began living with first spouse/partner.
na = Not applicable
 a = Omitted because less than 50 percent of the respondents began living with their first spouse/partner for the first time before reaching the beginning of the age group

Table 6.4 examines differences in the median age at first marriage for women and men by background characteristics. Rural women and men marry about one year earlier than urban women and men. Regional differentials show that women in the Upper East Region and men in the Volta Region marry about three years earlier than women and men in Greater Accra. Education has a marked impact on the age at marriage. For example, women age 25-49 with no education marry six years earlier than women with at least some secondary education. The same pattern is observed for men, although the educational difference among men is not as marked as among women. Women and men in the highest wealth quintile tend to marry later than their counterparts in the lower wealth quintiles.

6.4   AGE AT FIRST SEXUAL INTERCOURSE

Age at first marriage is sometimes seen as a proxy for a woman's first exposure to intercourse but the two events need not occur at the same time. Since women and men may engage in sexual relations prior to marriage, the age at first sexual intercourse is a more reliable estimate of a woman's exposure to the risk of pregnancy. In the survey, women and men were asked how old they were when they first had sexual intercourse.

Table 6.5 shows that the median age at first sexual intercourse for women age 25-49 years is 18.2 years and for men age 25-59 years it is 20.2 years. Nine percent of women and 4 percent of men reported having sexual intercourse by age 15. By age 18, almost half of women (48 percent) and one-fourth of men (25 percent) have had sexual intercourse. Sixty-one percent of women and 80 percent of men age 15-19

have never had sex. After age 24, nearly all women are sexually active. The 2003 GDHS data indicate that there has been little change over time in the median age at first sexual intercourse among women. However, age at first sexual intercourse among men has decreased. For example, the cohort of men age 20-24 had first sexual intercourse two years earlier (19.6 years) than the cohort of men age 55-59 (21.8 years).

Table 6.5 Age at first sexual intercourse

Table 6.6 shows differentials in median age at first sex by background characteristics. Urban women experience sexual intercourse for the first time about one year after their rural counterparts, but there is no difference in age at first sexual intercourse between urban and rural men. Women and men living in the Upper West Region experience first sexual intercourse at a later age than their counterparts in the other regions. Educated women and men and women who fall in the highest wealth quintile are also seen to initiate sexual intercourse at a later age than women and men with little or no education and women in the other wealth quintiles. In contrast, there is little difference in the age at first sexual intercourse among men by wealth quintile.

na = Not applicable

6.5   RECENT SEXUAL ACTIVITY

In the absence of contraception, the probability of pregnancy is related to the frequency of inter-course. Information on sexual activity, therefore, can be used to refine measures of exposure to pregnancy. Women and men were asked how long ago their last sexual activity occurred, to assess whether they had a sexual encounter in the last four weeks. The results are shown in Table 6.7.1 for women and Table 6.7.2 for men.

About two in five women age 15-49 were sexually active in the four weeks before the survey, 26 percent had been sexually active in the previous year but not in the previous month, and 13 percent had not been sexually active for one or more years. An additional 16 percent of women have never had sex.

The proportion of women who were sexually active in the four weeks before the survey increases with age from 14 percent at age 15-19 to 56 percent by age 40-44 and decreases thereafter to 48 percent among women age 45-49. Teenagers and women who are not currently in a marital union were less likely to be sexually active in the four weeks preceding the survey than older women and women who are married or living with a man. Three in five women who have been married 10 to 24 years were sexually active in the past four weeks. The proportion is slightly lower for those married less than 10 years or 25 or more years. Women who have been married more than once are more likely to have been sexually active in the past four weeks than women who have been married only once.

Women in urban areas are less likely to be sexually active over the past four weeks (38 percent) than those in rural areas (46 percent). The proportion of women who are sexually active in the four weeks preceding the survey is highest in the Eastern Region (48 percent) and lowest in Greater Accra (36 percent). Women with at least some secondary education are less likely to be sexually active than less educated women. As expected, women who are using a contraceptive method are more likely to be sexually active than women who are not using any method. Obviously, women who are sexually active are more likely to use a method, but it is also true that those who are using contraception probably feel freer to engage in sex because they are at a lower risk of pregnancy. Women in the highest wealth quintile are least likely to be sexually active in the past four weeks.

Almost half (45 percent) of the men interviewed were sexually active in the four weeks before the survey, while 22 percent had sex in the previous year but not in the previous month (Table 6.7.2). Ten percent had not been sexually active in the previous year and 23 percent had never had sex. As with women, sexual activity increases with age among men, with the highest level among men in their mid-40s and early 50s. Men in union are much more likely to be sexually active than those never in union. Fewer urban men (41 percent) reported recent sexual activity than rural men (48 percent). Recent sexual activity is highest in the Eastern Region (51 percent) and lowest in the Upper East (31 percent). Education and wealth do not appear to be related to recent sexual activity.

A comparison of data between the 2003 GDHS and the 1998 GDHS (GSS and MI, 1999) shows that there has been a decline in recent sexual activity among young men age 15-24 but an increase in recent sexual activity among older men. There has been little change in recent sexual activity among women over the past five years.

Table 6.7.1 Recent sexual activity: women

Percent distribution of women by timing of last sexual intercourse, according to background characteristics, Ghana 2003

6.6   POSTPARTUM AMENORRHOEA, ABSTINENCE, AND INSUSCEPTIBILITY

Postpartum amenorrhoea is the interval between the birth of a child and the return of the menstrual cycle. It is the period during which the woman becomes temporarily and involuntarily infecund following childbirth. Postpartum protection from conception can be prolonged by breastfeeding, which can lengthen the duration of amenorrhoea. Delaying the resumption of postpartum sexual relations can also prolong protection. The period of voluntary sexual inactivity after childbirth is referred to as postpartum abstinence. A woman is said to be insusceptible to the risk of pregnancy if she is either amenorrhoeic or abstaining from sexual intercourse following childbirth. Women who gave birth during the three years prior to the survey were asked about their breastfeeding practices, the duration of amenorrhoea, and postpartum sexual abstinence.

Table 6.8 shows that the median duration of amenorrhoea is 11 months, of abstinence 9 months, and of insusceptibility 14 months. The data show that all women are insusceptible to pregnancy during the first two months after a birth due to both postpartum amenorrhoea and postpartum abstinence. However, the contribution of abstinence to the period of insusceptibility starts decreasing after the second month after birth. At 10 to 11 months after birth, about half of all women are still amenorrhoeic, but only 41 percent are abstaining. By 14 to 15 months, a third of women are still amenorrhoeic, another third are abstaining, and only half are insusceptible because of the reduced combined effect of amenorrhoea and abstinence. At 20 to 21 months postpartum, mothers are just amenorrhoeic in one in ten births and the number abstaining is about a quarter (23 percent). By 34-35 months, the effect of postpartum amenorrhoea is almost completely wiped out and insusceptibility to pregnancy becomes low.

Table 6.8 Postpartum amenorrhea, abstinence and insusceptibility

Percentage of births in the three years preceding the survey for which mothers are postpartum amenorrhoeic, abstaining, and insusceptible, by number of months since birth, and median and mean durations, Ghana 2003

Months since birth	Percentage of births for which the mother is:			Number of births
	Amenorrhoeic	Abstaining	Insusceptible	
< 2	98.1	100.0	100.0	97
2-3	87.6	86.8	95.5	95
4-5	77.5	71.1	87.1	136

Median	10.8	8.8	13.8	na
Mean	12.1	12.8	16.0	na

Note: Estimates are based on status at the time of the survey.
 na = Not applicable

A comparison of data from the 1993, 1998, and 2003 GDHS surveys indicates that the median duration of postpartum amenorrhoea, abstinence, and insusceptibility decreased between 1993 (GSS and MI, 1994) and 1998 (GSS and MI, 1999) but remained unchanged between 1998 and 2003.

Table 6.9 shows the median durations of postpartum amenorrhoea, abstinence, and insusceptibility by background characteristics. Postpartum insusceptibility is shorter among urban than rural women. Postpartum insusceptibility is highest among women in the Upper East Region, due more to postpartum abstinence than amenorrhoea. In contrast, women from the Central Region are postpartum insusceptible primarily due to amenorrhoea rather than abstinence. There is an inverse relationship between the level of education and wealth on the one hand and women's insusceptibility to pregnancy on the other.

Table 6.9 Median duration of postpartum insusceptibility by background characteristics

Median number of months of postpartum amenorrhoea, postpartum abstinence, and postpartum insusceptibility following births in the three years preceding the survey, by background characteristics, Ghana 2003

Note: Medians are based on current status.

6.7   MENOPAUSE

Menopause marks the onset of infecundity and is another factor influencing the risk of pregnancy. Women are considered menopausal if they are neither pregnant nor postpartum amenorrhoeic, and have not had a menstrual period in the six months preceding the survey (Table 6.10). Nine percent of women age 30 and over are menopausal. As expected, the proportion of women who are menopausal increases with age from 2 percent among women age 30-34 to 47 percent among women age 48-49. The prevalence of menopause increases sharply after age 43.

Table 6.10 Menopause

Percentage of women age 30-49 who are menopausal, by age, Ghana 2003

Age	Percentage menopausal[1]	Number of women
30-34	2.2	802
35-39	1.2	722
40-41	3.7	269
42-43	11.3	233

Total	9.4	2,580

[1] Percentage of all women who are not pregnant and not postpartum amenorrhoeic whose last menstrual period occurred six or more months preceding the survey

FERTILITY PREFERENCES

7

Information on the fertility preferences of men and women provide a measure of the overall attitude of society towards childbearing and the general course of future fertility. This type of data is useful for family planning programmers to assess the need for contraception and the extent of unwanted and mistimed pregnancies. Data on fertility preferences can also be used to facilitate the objectives of the Ghana National Family Planning Programme, which was established to promote and facilitate couples' desires for the number of children they want to bear, with births spaced according to their preferences (Republic of Ghana, 1969).

In the 2003 GDHS, both women and men were asked a series of questions to ascertain their fertility preferences. Specific questions were asked about the desire to have another child, the length of time they would like to wait before having another child, and what they considered to be the ideal number of children. The information collected makes it possible to quantify fertility preferences and, in combination with data on contraceptive use, allow the estimation of unmet need for family planning, both for spacing and for limiting births.

7.1 DESIRE FOR MORE CHILDREN

Table 7.1 shows fertility preferences among currently married women and men by the number of living children at the time of the survey. There is considerable desire among currently married Ghanaians to control the timing and number of births. Thirty-eight percent of currently married women would like to wait for two years or more for the next birth, and 36 percent do not want to have another child or are sterilised. About a fifth (18 percent) would like to have a child soon (within two years). The remaining women are uncertain about their fertility desires or say they are unable to get pregnant (infecund). A similar pattern is observed for currently married men.

Table 7.1 also shows that fertility preferences are closely related to the number of children a woman has. The vast majority (63 percent) of currently married women without a child would like to have one soon. Nevertheless, they show a greater interest in controlling the pace of childbearing once they have a child; almost two-thirds (63 percent) of women with one child want to delay their next birth. Interest in controlling the number of births grows rapidly as the number of children increases; the proportion of married women wanting no more children or who are sterilised rises from 4 percent among women with one child to 75 percent among women with six or more children. Men without a child are twice as likely to want a child later than women. At the same time, women who have not started childbearing are much more likely to want a child within two years than men (63 and 47 percent, respectively).

Table 7.1 Fertility preferences by number of living children

Percent distribution of currently married women and men by desire for children, according to number of living children, Ghana 2003

[1] Includes current pregnancy
[2] Wants next birth within two years
[3] Wants to delay next birth for two or more years

A comparison of the data over the four GDHS surveys show that the desire to space births among currently married women has declined in the past 15 years, from 45 percent in 1988 (GSS and IRD, 1989) to 38 percent in 2003. However, this change has been minimal in the past ten years. On the other hand, the desire to limit (excluding sterilised women) has increased from 23 percent in 1988 to 34 percent in 2003. Again this change has been minimal over the past ten years.

Table 7.2 shows the percentage of currently married women and men who want no more children (or are sterilised) by the number of living children and background characteristics. Urban women are more likely than rural women to want no more children regardless of the number of children they already have, although the overall urban-rural difference is slightly less then one percentage point, a pattern that is similar for men as well.

Note: Women and men who have been sterilised are considered to want no more children. An asterisk indicates that a figure is based on fewer than 25 un-weighted cases and has been suppressed. Figures in parentheses are based on 25-49 unweighted cases.
[1] Includes current pregnancy

Women and men residing in the Eastern, Volta, Greater Accra, Central, and Western regions are more likely than women and men in the other regions to want to limit the number of children they have (38-47 percent). The desire to limit childbearing among women is lowest in the Northern Region (15 percent).

The percentage of men who do not want any more children increases with the level of education. For example, the desire to limit childbearing rises from 17 percent among men with no education to more than 40 percent among men with at least Middle/JSS education; however, educational difference among women is marked only between women with no education (32 percent) and those with some education (37-41 percent). Educational differences among women are, however, striking when the number of living children is taken into account. For example, among women with three children, only 17 percent of women with no education want no more children compared with 69 percent of women with secondary or higher schooling.

A similar male-female pattern is observed by wealth quintiles. In general, women and men who are from the lowest wealth quintile are least likely to want to limit the number of children that they want, with quintile differentials more striking among men than women.

7.2 NEED FOR FAMILY PLANNING SERVICES

Currently married women who say that they do not want any more children or that they want to wait two or more years before having another child, but are not using contraception, are considered to have an unmet need for family planning. Women who are using family planning methods are said to have a met need for family planning. Women with unmet need and met need together constitute the total demand for family planning.

Table 7.3 shows the need for family planning among currently married women by background characteristics. Thirty-four percent of married women have an unmet need for family planning. Unmet need for spacing is higher than unmet need for limiting children (22 and 12 percent, respectively). Table 7.3 also shows that one in four currently married women is using a method of contraception, with 14 percent using for spacing and 11 percent using for limiting. The total demand for family planning among women is 59 percent, 36 percent with a need for spacing and 24 percent with a need for limiting. Forty-three percent of the demand for family planning is currently being met, implying that the needs of more than one in two women are currently not being met.

Comparison of data from the 1998 and 2003 GDHS surveys suggests that there has been little change in the unmet need among currently married women over the past five years. The total demand for family planning and the percentage of demand satisfied increased by 7 percent, each, over the five-year period.

[1] Unmet need for spacing includes pregnant women whose pregnancy was mistimed, amenorrhoeic women who are not using family planning and whose last birth was mistimed, and fecund women who are neither pregnant nor amenorrhoeic and who are not using any method of family planning and say they want to wait 2 or more years for their next birth. Also included in unmet need for spacing are fecund women who are not using any method of family planning and say they are unsure whether they want another child or who want another child but are unsure when to have the birth unless they say it would not be a problem if they discovered they were pregnant in the next few weeks. Unmet need for limiting refers to pregnant women whose pregnancy was unwanted, amenorrhoeic women whose last child was unwanted, and fecund women who are neither pregnant nor amenorrhoeic and who are not using any method of family planning and who want no more children. Excluded from the unmet need category are pregnant and amenorrhoeic women who became pregnant while using a method (these women are in need of a better method of contraception).

[2] Using for spacing is defined as women who are using some method of family planning and say they want to have another child or are undecided whether to have another. Using for limiting is defined as women who are using and who want no more children. Note that the specific methods used are not taken into account here.

Unmet need generally declines with age, with the decline sharper among younger (15-29) than older (35-49) women. As can be seen from the table, younger women have a higher unmet need for spacing, while older women have a greater unmet need for limiting. Rural women have a higher unmet need for family planning than their urban counterparts (38 percent compared with 28 percent). It is also interesting to note that rural women have higher unmet need for both spacing and limiting than their urban counterparts. Unmet need is highest in the Central Region (50 percent) and lowest in the Upper West (25 percent). Not surprisingly, the percentage of demand satisfied is highest in Greater Accra (52 percent) and lowest in the Upper East and Central regions (23 percent each). With the exception of Greater Accra, the unmet need for spacing is higher than the unmet need for limiting in all regions.

Women with secondary or higher education have a lower unmet need for family planning (24 percent) than women with primary education and those with no education whose unmet need for family planning is 40 and 35 percent, respectively. Total demand for family planning is highest for women with primary education rather than women with no education, 66 percent compared with 50 percent. The percentage of demand satisfied ranges from 30 percent among women with no education to 62 percent for women with secondary or higher level education.

The unmet need for family planning is highest among women in the lowest wealth quintile and lowest among women in the highest wealth quintile (41 and 24 percent, respectively). For all the five wealth quintiles, the unmet need for spacing is higher than the unmet need for limiting. Also, the percentage of demand satisfied ranges from 26 percent for women in the lowest wealth quintile to 59 percent for women in the highest wealth quintile.

7.3   IDEAL FAMILY SIZE

Information on what men and women believe to be their ideal family size was elicited through two questions. Respondents who had no living children were asked, "If you could choose exactly the number of children to have in your whole life, how many would that be?" Respondents who had children were asked, "If you could go back to the time you did not have any children and could choose exactly the number of children to have in your whole life, how many would that be?" These questions are based on hypothetical situations; therefore, the responses to them are expected to in part reflect societal norms prevalent in the past as well as at present. Nevertheless, even though these questions are based on hypothetical situations, they give an idea of the total number of children women who have not started childbearing will have in the future, while among older and high parity women, these data provide a measure of the level of unwanted fertility.

Table 7.4 shows that 98 percent of women and men gave a numeric response to the questions on ideal number.

Table 7.4 Ideal number of children

[1] Includes current pregnancy
[2] Means are calculated excluding the women and men giving non-numeric responses

The mean ideal number of children for all women is 4.4, while for men it is 4.8, indicating that men's ideal number of children is slightly larger than women's. Both currently married women and men prefer a larger ideal family size than all women and men. There may be two principal reasons for this pattern. To the extent that women and men are able to implement their fertility desires, those who want smaller families will tend to achieve smaller families. Some women and men who have children may have difficulty admitting that they would like to have fewer children than they actually have and are likely to report their actual number of children as their preferred number. For the most part, the pattern in expressed desire by ideal number is similar among women and men. However, the percentages for

women and men diverge beyond an ideal number of three children. Thirty-five percent of all women express a desire for four children compared with 29 percent of all men. On the other hand 11 percent of women prefer an ideal number of 5 children compared with 15 percent of men.

The preference for a larger number of children is higher for men than women irrespective of the number of living children. Ideal number increases with the number of living children and ranges from 3.7 for all women without any children to 5.8 for those with at least 6 children. As with women, the mean ideal number of children among all men increases with the number of children and ranges from 4.1 among those without a child to 7.1 among those who already have 6 or more children.

Data from GDHS surveys conducted over the past 15 years shows that, although there has been a decline in ideal family size among currently married women over time, from a mean of 5.5 children in 1988 (GSS and MI, 1989) to 4.8 children in 2003, there has been little change in the past 10 years. In fact, there appears to be a slight increase in the ideal family size desired by both women and men over the past five years (GSS and MI, 1999).

Table 7.5 shows the mean ideal number of children for all women and men by age according to background characteristics. The ideal family size increases with age, from 3.8 children among women age 15-19 to 5.4 among women age 45-49. For men in these age groups, the mean ideal number ranges from 4.2 to 6.1. This pattern suggests a trend towards lower ideal family size. The ideal family size for both women and men is higher in rural than urban areas. The ideal size is highest in the Northern Region (6.9 for women and 8.2 for men) and relatively high for the other two northern regions. This confirms the findings that women and men residing in the three northern regions have a preference for large families. Women and men residing in Greater Accra have the lowest ideal family size. There are also variations in the ideal family size by level of education. Across all age groups, the ideal family size decreases with increasing

levels of education. A similar pattern is observed by wealth quintiles.

7.4   FERTILITY PLANNING

Wanted fertility can be measured in two ways. Responses to a question about children born in the five years preceding the survey (and any current pregnancy) are used to determine whether the pregnancy was planned (wanted then), wanted but at a later time (mistimed), or unwanted (not wanted at all). The answers to these questions provide some insight into the degree to which couples are able to control fertility. Wanted fertility is calculated in the same manner as the actual total fertility rate, but unwanted births are excluded from the numerator.

Table 7.6 shows the percent distribution of births (including current pregnancy) in the five years preceding the survey by fertility planning status, according to birth order and mother's age at birth. The data show that two-fifths of births in the five years preceding the survey are unplanned—24 percent were mistimed (wanted later) and 16 percent were unwanted. The proportion of planned births increases between the first and second birth and then declines for subsequent births.

Table 7.6 Fertility planning status

Percent distribution of births in the five years preceding the survey (including current pregnancy), by fertility planning status, according to birth order and mother's age at birth, Ghana 2003

| Birth order and mother's age at birth | Planning status of birth | | | | | Number of births |
	Wanted then	Wanted later	Wanted no more	Missing	Total	
Birth order						
1	57.9	25.7	16.2	0.2	100.0	910
2	66.3	25.8	7.3	0.6	100.0	785
3	63.1	26.2	9.4	1.3	100.0	640
4+	55.8	21.7	21.7	0.8	100.0	1,723
Mother's age at birth						
<20	42.0	37.0	20.7	0.3	100.0	458
20-24	58.9	29.8	10.7	0.5	100.0	989
25-29	66.9	21.6	11.1	0.5	100.0	1,025
30-34	64.4	21.7	13.2	0.7	100.0	772
35-39	58.1	16.8	23.8	1.3	100.0	546
40-44	50.8	12.7	35.0	1.5	100.0	222
45-49	53.0	12.8	32.1	2.1	100.0	47
Total	59.4	24.1	15.7	0.7	100.0	4,058

The proportion of unplanned births has slightly decreased from 42 percent in 1993 to 36 percent in 1998 but increased to 40 percent in 2003. What is more troubling, however, is the fact that the proportion of births that are unwanted has increased rather dramatically from the 1993 and 1998 level of 9 percent to 16 percent in 2003.

Table 7.7 provides information on total wanted fertility rates and the actual total fertility rates for the three years preceding the survey, by select background characteristics. Unwanted births are defined as births that exceed the number considered ideal. Women who did not report a numeric ideal family size were assumed to want all their births. The total wanted fertility rate represents the level of fertility that would have prevailed in the three years preceding the survey if all unwanted births were prevented. A

comparison of the total wanted fertility and actual total fertility rate suggests the potential demographic impact of the elimination of unwanted births.

The total wanted fertility rate, which stood at 4.2 in 1993, fell to 3.7 in 1998 and remained at 3.7 in the three years preceding the 2003 survey. During the same period, the total fertility rate fell from 5.2 children per woman in 1993 to 4.4 in 1998 and remained unchanged at 4.4 in 2003 suggesting a narrowing between desired and actual fertility over the past 10 years.

The wanted fertility rate in rural areas is two children more than in urban areas. The gap between wanted and realised fertility in rural areas is larger than in urban areas, suggesting that urban women may be better able to translate their ideal family size to realised family size.

At the regional level, women in Greater Accra desire the least number of children (2.4) in contrast to their counterparts in the Northern Region who want 6.5 children. However, the gap between desired and actual fertility is the same between these two regions. The largest gap between wanted and realised fertility is observed in the Central and Eastern regions (about 1.5 children), suggesting that women in these regions are less able to translate their desired family size in practice.

Women's education has an inverse relationship with levels of both wanted and actual fertility, although the difference between the two is higher among those with primary education (1.3) than among those with no education (0.8). There is also an inverse relationship between wealth and wanted fertility, with the gap between wanted and actual fertility widest among women who belong to the second wealth quintile.

Table 7.7 Wanted fertility rates		
Total wanted fertility rates and total fertility rates for the three years preceding the survey, by background characteristics, Ghana 2003		
Background characteristic	Total wanted fertility rate	Total fertility rate
Residence

Middle	4.1	4.9
Fourth	2.6	3.3
Highest	2.4	2.8
Total	3.7	4.4

Note: Rates are calculated based on births to women age 15-49 in the period 1-36 months preceding the survey. The total fertility rates are the same as those presented in Table 4.2.

7.5   IDEAL FAMILY SIZE AND UNMET NEED BY WOMEN'S STATUS

An increase in women's status and empowerment is recognised as important in the effort to reduce fertility through at least two main pathways: its association with desired family size and its positive association with women's ability to meet their own family-size goals through the effective use of contraception. Table 7.8 shows how women's ideal family size and their unmet need for contraception vary by the three indicators of women's empowerment—number of decisions in which the respondent has final say, number of reasons for which a woman can refuse to have sexual relations with her husband, and number of reasons for which the respondent feels a husband is justified in beating his wife.

Table 7.8 shows that the mean ideal number of children is lowest among women who believe that wife-beating is not justified for any reason at all and progressively increases with the number of reasons women believe that it can be justified. Unmet need is also lowest among women who believe that wife-

beating is not justified for any reason at all. There is no clear pattern between ideal family size or unmet need and the other two measures of women's status.

Table 7.8 Ideal number of children and unmet need by women's status

Mean ideal number of children and unmet need for spacing and limiting among all women, by women's status indicators, Ghana 2003

INFANT AND CHILD MORTALITY

<div style="text-align: right; font-size: 2em; font-weight: bold;">8</div>

Chapter 8 deals with levels, trends, and differentials in neonatal, postneonatal, infant, child, and under-five mortality in Ghana. The data used in measuring these childhood mortality rates were collected from the birth history section of the Women's Questionnaire in the 2003 GDHS. Women of reproductive age (15-49) were asked the number of biological sons and daughters who live with them, the number living elsewhere, and the number who have died. In addition, for each live birth, women were asked for the sex, date of birth, whether the birth was single or multiple, and the survival status. Information about age for living children, and for deceased children, age at death, was also collected.

Measures of childhood mortality are used for a number of purposes. For instance, childhood mortality in general and infant mortality in particular are often used as broad indicators of social development or as more specific indicators of health status. Measures of childhood mortality are also useful in population projections. Studies of its characteristics such as age pattern and socio-economic and demographic differentials are used to highlight factors that promote child survival as well as those that are detrimental to it. Consequently, mortality analyses are helpful in identifying promising directions for health programmes and advancing child survival efforts.

8.1 DEFINITION, DATA QUALITY AND METHODOLOGY

Childhood mortality estimates measure the risk of dying from birth up to age five. The rates of childhood mortality presented in this chapter are defined as follows:

Neonatal mortality (NN): the probability of dying between birth and the first month of life

Postneonatal mortality (PNN): the difference between infant and neonatal mortality

Infant mortality ($_1q_0$): the probability of dying between birth and exact age one

Child mortality ($_4q_1$): the probability of dying between exact ages one and five

Under-five mortality ($_5q_0$): the probability of dying between birth and exact age five.

All rates are expressed per 1,000 live births, except child mortality, which is expressed per 1,000 children surviving to 12 months of age.

The reliability of mortality estimates depends on the sampling variability of the estimates and on nonsampling errors. Sampling errors are presented in Appendix B. Nonsampling errors arise from problems associated with the quality of data collection and include the completeness with which births and deaths are reported and recorded. The most common problems are misreporting of age at death, misreporting of dates of birth, and event underreporting (of both the birth and death of a child). The possible occurrence of these data problems in the 2003 GDHS is discussed with reference to the data quality tables in Appendix C.

A typical problem with survey data is the misreporting of infant deaths, that occur in the late postneonatal period, as deaths at 12 months or one year of age (digit preference in the reporting of age). Such misreporting results in underestimation of the infant mortality rates and overestimation of child mortality rates. Table C.6 in Appendix C displays some digit preferences in reported deaths at 12 months

or one year. This "heaping" took place in spite of the care taken in the GDHS to minimise errors of this nature by insisting that age at death be recorded in days if the death took place within one month after birth, in months if the child died within 24 months of birth, and in years if the child died between ages two and five. Nevertheless, age heaping at 12 months is not markedly different from the level seen in the data collected in the previous GDHS surveys.

Misreporting of the date of birth of children is common in many surveys that include both demographic and health information for children born since a specified date. The effect of such an error is to distort time trends in fertility and mortality. In the 2003 GDHS, the cutoff date for asking health questions was 1998, that is, for births since January 1998. An examination of Table C.4 suggests that there is evidence of misreporting of dates of birth for both living and deceased children. The calendar year ratios for living and deceased children are 82 and 48 percent, respectively, for 1998, compared with 116 and 153 percent, respectively, in 1997. The deficit in calendar year 1998 is believed to be the result of "aging" of children by interviewers who want to avoid collecting health data information for children. The transference of children and especially deceased children out of the five-year period preceding the survey is likely to understate the true level of childhood mortality for that period. The data also show heaping in 1999 and 2000, although this is not as severe as in 1997.

Event underreporting is usually more severe for deaths that occur early in infancy. Omission of deaths may also be more common among women who have had several children, or in cases where the death took place a long time ago. In order to assess the impact of omission on measures of child mortality, two indicators are used: the percentage of deaths that occurred under seven days to the number that occurred under one month and the percentage of neonatal to infant deaths. It is hypothesised that omission will be more prevalent among those who died immediately after birth than those who lived longer and that it will be more serious for events that took place in the distant past rather than those in the more recent past. Table C.5 shows that the percentage of early neonatal deaths ranges from 77 percent for the 15-19 years prior to the survey to 85 percent for the 5-9 years before the survey and 83 percent for the period 0-4 years before the survey. These results are similar to those found in the 1988 (GSS and MI, 1998), 1993 (GSS and MI, 1994), and 1998 (GSS and MI, 1999) GDHS surveys. Similarly, Table C.6 shows that neonatal deaths comprise 57 to 69 percent of all infant deaths. This is considered plausible.[1] Over time, the figures vary within a narrow range for the 20 years prior to the survey, suggesting that there has not been selective omission of early infant deaths.

In addition to recall errors for the more distant retrospective periods, there are structural reasons for limiting mortality estimation to recent periods, preferably to the 0-4, 5-9, and 10-14 years before the survey. In fact, except for the first period, the others are slightly biased estimates because they are based on child mortality experience of women age 15-44 and 15-39 respectively instead of women age 15-49 as in the 0-4 years prior to the survey period. Therefore, estimating mortality for the periods further than 10-15 years before the survey is not advisable.

8.2   LEVELS AND TRENDS IN INFANT AND CHILD MORTALITY

Table 8.1 shows mortality rates for the 15 years preceding the survey in three five-year periods. Under-five mortality in Ghana is 111 deaths per 1,000 live births in the most recent five-year period. This means one in every nine Ghanaian children dies before reaching age five. Nearly three in five of these deaths occur in the first year of life—infant mortality is 64 deaths per 1,000 live births and child mortality

---

[1] There are no model mortality patterns for the neonatal period. However, one review of data from several developing countries concluded that at levels of neonatal mortality of 20 per 1,000 or higher, approximately 70 percent of neonatal deaths occur within the first six days of life (Boerma, 1988).

is 50 deaths per 1,000 children age one year. Neonatal mortality is 43 deaths per 1,000 live births in the most recent five-year period, while postneonatal mortality is 21 deaths per 1,000 live births. Neonatal deaths account for two-thirds of the deaths in infancy.

Table 8.1 Early childhood mortality rates

Neonatal, postneonatal, infant, child, and under-five mortality rates for five-year periods preceding the survey, Ghana 2003

Years preceding the survey	Neonatal mortality (NN)	Postneonatal mortality[1] (PNN)	Infant mortality $(_1q_0)$	Child mortality $(_4q_1)$	Under-five mortality $(_5q_0)$
0-4	43	21	64	50	111
5-9	39	26	65	46	108
10-14	38	26	64	43	104

[1] Computed as the difference between the infant and neonatal mortality rates

Mortality trends can be examined in two ways: by comparing mortality rates for three five-year periods preceding a single survey, and by comparing mortality estimates obtained from various surveys. However, mortality data have to be interpreted with caution since sampling errors associated with mortality estimates are large.

Data from the 2003 GDHS show that infant mortality has remained constant over the 15-year period preceding the survey at about 64-65 deaths per 1,000 live births. However, there is substantial variation when the infant mortality rates are split into their component neonatal and postneonatal mortality rates. Postneonatal mortality declined slightly from 26 per 1,000 in the 5-14 years before the survey to 21 per 1,000 live births in the 0-4 years before the survey. Over the same period, neonatal mortality increased from 38 per 1,000 live births to 43 per 1,000 live births. Both child mortality and under-five mortality increased from 43 per 1,000 children to 50 per 1,000 children, and from 104 per 1,000 births to 111 per 1,000 births, over the same period, respectively. All these changes are very small and are not statistically significant. In other words, according to these figures, childhood mortality has remained more or less constant over the 1988 to 2003 period. With declining infant mortality, the proportion of neonatal to infant mortality is expected to increase. However, in the case of the 2003 GDHS data, contrary to expectation, infant mortality remained constant over the 15-year period, while the proportion of neonatal to infant mortality increased. A reduction in postneonatal mortality may reflect an improvement in the socio-economic situation of the population, leading to increased vaccination coverage and improved maternal and child health care. The deterioration in neonatal mortality is, however, more difficult to explain.

When data from the four GDHS surveys (conducted in 1988, 1993, 1998, and 2003) are compared (Table 8.2 and Figure 8.1), for the most recent five-year period, the marked decline in both infant and under-five mortality observed in the three earlier surveys (1984-1998) appears to have halted during the period 1999-2003. This is caused principally by an increase in the neonatal mortality rate from about 30 per 1,000 for the 0-4 years preceding the 1998 GDHS to 43 per 1,000 during the same period prior to the 2003 GDHS (GSS and MI, 1999). It is reassuring that the under-five mortality rate for the period 5-9 years before the 2003 GDHS (108) is identical to the rate 0-4 years before the 1998 GDHS.

The apparent slowing down in mortality decline signifies the difficulties the socio-economic situation in general and the health system in particular are facing in achieving the Ghana Poverty Reduction Strategy, which targets an infant mortality rate of 50 per 1,000 and an under-five mortality rate of 95 by 2005 (World Bank, 2003).

Ghana 1988-2003
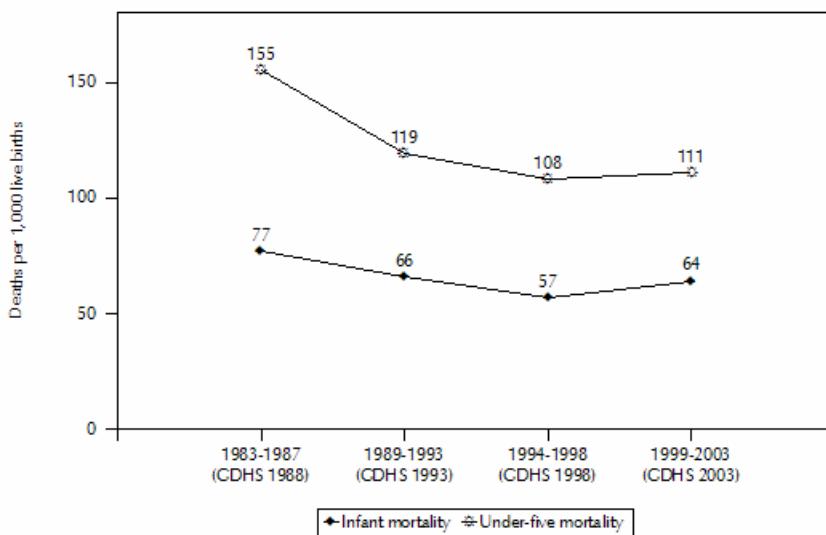

Table 8.2 Trends in early childhood mortality rates			
Infant and under-five mortality, Ghana 1983-2003			
Survey year	Approximate calendar period	Infant mortality ($_1q_0$)	Under-five mortality ($_5q_0$)
1988	1983-1987	77	155
1993	1989-1993	66	119
1998	1994-1998	57	108
2003	1999-2003	64	111

8.3   SOCIO-ECONOMIC DIFFFERENTIALS IN MORTALITY

Table 8.3 and Figure 8.2 show differentials in childhood mortality by four socio-economic variables: residence, region, mother's education, and wealth quintile. When interpreting mortality data, it is useful to bear in mind that sampling errors are quite large. To ensure a sufficient number of cases for statistical reliability, mortality rates are calculated for a ten-year period.

Socio-economic characteristics are highly correlated with one another and with bio-behavioural characteristics, and their impact is better analysed within a multivariate framework. However, such an analysis is beyond the scope of this report. Therefore, caution must be exercised in interpreting the bivariate results shown in Table 8.3.

Place of residence, whether urban or rural, is defined at the time of interview. Where internal migration is high, births of migrants may have occurred in the place of previous residence. The mortality estimates of the current place of residence are, therefore, likely to be slightly biased. In the absence of data that would allow the classification of exposure and deaths according to the place of residence at the time of the event, the assumption is made that the extent of bias is marginal.

Table 8.3 Early childhood mortality rates by socio-economic characteristics

Neonatal, postneonatal, infant, child, and under-five mortality rates for the ten-year period preceding the survey, by background characteristic, Ghana 2003

Highest	42	15	58	33	88
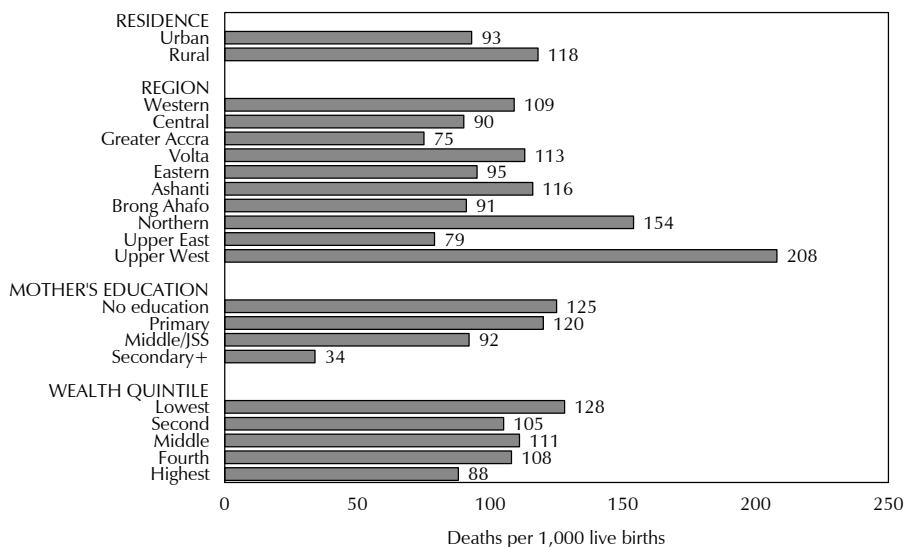

Note: Rates based on 250 to 499 exposed persons are in parentheses.
[1] Computed as the difference between the infant and neonatal mortality rates

Mortality levels in rural areas are considerably and consistently higher than in urban areas. For instance, under-five mortality in rural areas is 118 per 1,000 live births compared with 93 for urban areas. The urban-rural gap is most notable for postneonatal mortality, which is considerably higher in rural areas (27 per 1,000 births) than in urban areas (17 per 1,000 births).

Marked regional differentials in under-five mortality are also observed in Table 8.3. For example, under-five mortality ranges from a low of 75 per 1,000 live births in Greater Accra to a high of 208 per 1,000 live births in the Upper West Region.

As expected, mother's education is inversely related to a child's risk of dying. Under-five mortality among mothers with no education (125 per 1,000 live births) is noticeably higher than among women with middle/JSS level of education (92 per 1,000 live births). The direct association observed between education and under-five mortality is, however, not reproduced at the infant mortality level. Children of women with no education appear to have a lower risk of dying than those with primary education.

Figure 8.2
Under-Five Mortality by Background Characteristics

Note: Rates are for the 10-year period preceding the survey.   GDHS 2003

Children in the highest wealth quintile exhibit the lowest mortality rate for all categories of mortality, with the exception of neonatal mortality, which is lowest among the poorest segment of the population.

8.4   DEMOGRAPHIC CHARACTERISTICS AND CHILD MORTALITY
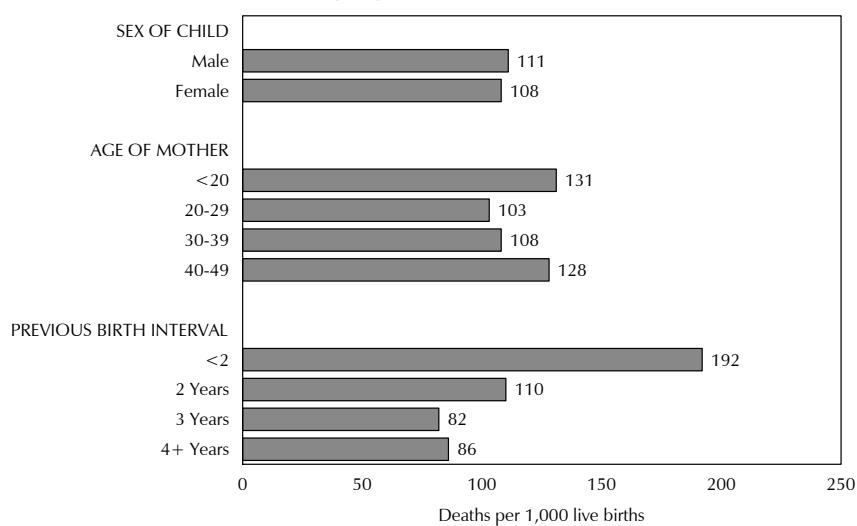

Studies have shown that a number of demographic factors are strongly associated with the survival chances of young children. These factors include sex of the child, age of the mother at birth, birth order, length of the preceding birth interval, and the size of the child at birth. Table 8.4 shows the relationship between childhood mortality and these demographic variables. Again, for all variables except birth size, mortality estimates are calculated for a ten-year period before the survey to reduce sampling variability. However, mortality rates by birth size are for the five years preceding the survey since information on birth size was collected only for children born in the last five years.

Childhood mortality rates are generally higher for males than females (Figure 8.3). With the exception of child mortality, male mortality exceeds female mortality at all levels (Table 8.4). Data from World Fertility Surveys and DHS surveys indicate that births to young mothers (under age 20 years) and older mothers (35 years and over) experience an elevated risk of mortality. Data from the 2003 GDHS confirm the expected curvilinear relationship between mother's age at birth and mortality.

First births and higher order births generally face an elevated risk of mortality. Data from the 2003 GDHS confirm this pattern for the most part. With the exception of postneonatal mortality, births of order seven and higher experience the highest levels of childhood mortality. Neonatal, infant, and under-five mortality is lowest for second and third order births.

Mortality among children is negatively associated with the length of the previous birth interval and this is especially the case when the birth interval is less than two years. As seen from the data, this is

Figure 8.3
Under-Five Mortality by Socio-Economic Characteristics

Note: Previous birth interval excludes first-order births; rates are for the
10-year period preceding the survey.

GDHS 2003

true at all levels of mortality. For example, neonatal mortality for children born at less than a two-year interval is two to three times higher than for children born after an interval of two years or more.

A child's size at birth has often been found to be an important determinant of its survival chances in infancy. The majority of births in Ghana take place outside a health facility. Babies born in a non-institutional setting are seldom weighed at birth, and the only measure of their size at birth is the mother's assessment of their size. The data show that infant mortality is 50 percent higher among babies assessed as small or very small than babies assessed as average or larger at birth. The difference in infant mortality is predominantly due to neonatal mortality, which is almost twice as high among small or very small babies as among average or larger babies.

8.5   WOMEN'S STATUS AND CHILD MORTALITY

In Ghana, as in most societies, women are the primary child caregivers. As such, their status can have a direct impact on the health status and survival of their children. Empowered women are in a better position to make informed decisions about their own and their children's health. The 2003 GDHS included three proxy measures of women's status: their participation in household decisionmaking, their attitude towards a woman's ability to refuse sex with her husband, and their attitude towards wife-beating.

Table 8.5 shows childhood mortality rates tabulated by the three measures of women's status. Mortality rates are consistently higher for children whose mothers have no say in any household decision-making. For example, under-five mortality is 133 deaths per 1,000 births among women who have no say in any household decisions compared with 104 deaths per 1,000 births among women who have a say in all five household decisions. Infant mortality and its two component rates are higher among women who believe that a wife cannot refuse sex with her husband for any reason, but this relationship is not clear for

Table 8.5 Early childhood mortality rates by women's status

Neonatal, postneonatal, infant, child, and under-five mortality rates for the ten-year period preceding the survey, by women's status indicators, Ghana 2003

Women's status indicator	Neonatal mortality (NN)	Postneonatal mortality[1] (PNN)	Infant mortality ($_1q_0$)	Child mortality ($_4q_1$)	Under-five mortality ($_5q_0$)
Number of decisions in which woman has final say[2]

[2] Alone or jointly with others

child and under-five mortality. Postneonatal, child, and under-five mortality rates are also clearly lower among women who believe that wife-beating is not justified for any reason at all, but this relationship is not clear for neonatal and infant mortality.

8.6   PERINATAL MORTALITY

Women in the 2003 GDHS were asked to report on any pregnancy loss that occurred in the five years preceding the survey. For each pregnancy that did not end in a live birth, the duration of pregnancy was recorded. In this report, perinatal deaths include pregnancy losses of at least seven months' gestation (stillbirths) and deaths to live births within the first seven days of life (early neonatal deaths). The perinatal mortality rate is the sum of stillbirths and early neonatal deaths divided by the sum of all stillbirths and live births. Information on stillbirths and deaths to infants within the first week of life are highly susceptible to omission and misreporting. Nevertheless, retrospective surveys in developing countries provide more representative and accurate perinatal death rates than the vital registration system.

The perinatal mortality rate serves as a good indicator of the state of health in general and at delivery in particular. It reflects the level of utilisation of health services and the ability to cope with demands of childbirth and thereby delivery of a healthy baby. Data in Table 8.6 show that out of the 3,679 reported pregnancies of at least seven months' gestation, 40 were stillbirths and 129 were early neonatal deaths, yielding an overall perinatal mortality rate of 46 per 1,000 pregnancies.

Perinatal mortality is highest among mothers age 30-39 (58 per 1,000 pregnancies) and lowest among mothers age 20-29 (37 per 1,000 pregnancies). Perinatal mortality is also relatively higher among teenage mothers (52 per 1,000 pregnancies). The higher perinatal mortality among both young and older women may be a reflection of accessing antenatal services later rather than early in their pregnancy, women's inability to use antenatal services effectively either because they lack the social and financial means to enable them to use the existing facilities, or in the case of very young women, because they are less biologically ready for safe childbearing.

Perinatal mortality is highest when the previous pregnancy interval is less than 15 months (90 per 1,000 pregnancies). Perinatal mortality is also higher among women residing in rural than urban areas (51 and 37 per 1,000 pregnancies, respectively). A wide regional variation in perinatal mortality is also evident with women in the Western, Ashanti, Volta, and Central regions experiencing levels higher than the national average. Surprisingly, women in the Upper East and Northern regions reported the lowest rates (26 and 29 per 1,000 pregnancies, respectively). Contrary to expectations, there is no clear relationship between perinatal mortality and women's education or the wealth index.

8.7   HIGH-RISK FERTILITY BEHAVIOUR

Children's survival chances are associated with certain characteristics of fertility behaviour. These characteristics are of particular importance in this section because they are easily avoidable at a relatively low cost. Infants and children have an elevated risk of dying if their mothers are too young (under 18 years of age) or too old (over 35 years old), if they are born after too short a birth interval (less than 24 months), and if they are of high birth order (has three or more children). Although first births are commonly associated with higher mortality risk, they are not included in the high-risk category because the risks associated with first births are unavoidable.

Table 8.7 shows the percent distribution of children born in the five years preceding the survey and the percent distribution of currently married women, by risk factors. The table also shows the risk ratio of dying for children, by comparing the proportion of dead children in each risk category with the proportion of dead children not in any high-risk category.

Subtotal	22.1	1.64	45.3
In any avoidable high-risk category	52.9	1.55	73.6
Total	100.0	na	100.0
Number of births	3,639	na	3,549

Note: Risk ratio is the ratio of the proportion dead among births in a specific high-risk category to the proportion dead among births not in any high-risk category.
na = Not applicable
[1] Women are assigned to risk categories according to the status they would have at the birth of a child if they were to conceive at the time of the survey: current age less than 17 years and 3 months or older than 34 years and 2 months, latest birth less than 15 months ago, or latest birth being of order 3 or higher
[2] Includes the category age <18 and birth order >3
[a] Includes sterilised women

The first column in Table 8.7 shows the percentage of births occurring in the five years before the survey that fall into the various risk categories. Slightly more than half (53 percent) of births in Ghana have elevated mortality risks, which are avoidable, and almost three in ten (28 percent) were not in any high-risk category. Among those who are at risk, 31 percent of births are in a single high-risk category,

while 22 percent of births are in a multiple high-risk category. In general, risk ratios are higher for children in a multiple high-risk category than for those in a single high-risk category.

The most vulnerable births are those to women who are age 35 or older, with a birth interval less than 24 months and birth order three or higher. These children are nearly four times more likely to die than children not in any high-risk category. Fortunately, less than 2 percent of births fall into this category. Twenty-one percent of births occur to mothers who have three or more births, and another 16 percent of births occur to mothers who are 35 years or older and have had three or more children. These children are about one and a half times as likely to die as children without any risk.

The last column of Table 8.7 shows the distribution of currently married women who have the potential for having a high-risk birth by category. This column is purely hypothetical and does not take into consideration the protection provided by family planning, postpartum insusceptibility, and prolonged abstinence. However, it provides an insight into the magnitude of high-risk fertility behaviour. Three in four women are potentially at risk of giving birth to a child with an elevated risk of mortality. Nearly one in three of these women is or would be too old, and have or would have too many children. A substantially higher proportion of women have the potential of having a birth in a multiple high-risk category than in a single high-risk category.

MATERNAL AND CHILD HEALTH

9

This chapter presents findings from the 2003 GDHS in three areas of importance to maternal and child health, including information on antenatal, delivery, and postnatal care, children's vaccinations, and common childhood illnesses and their treatment. Combined with information on childhood mortality, this information can be used to identify subgroups of women and children who face increased risk because of non-use of maternal and child health (MCH) services, and to provide information to assist in the planning of appropriate improvements in services. Data were obtained for all live births that occurred in the five years preceding the survey. Wherever possible, data from the 2003 GDHS are compared with data from the three earlier DHS surveys in Ghana, conducted in 1988, 1993, and 1998. However, analysis of trends in maternity care indicators is complicated by the fact that previous GDHS surveys asked questions on antenatal care and tetanus injections for all births, whereas the 2003 survey confined these questions to only the most recent birth. In addition, the questions on maternity care and children's health referred to varying periods (sometimes five and sometimes three years) preceding the survey. While it is possible to adjust for some of these inconsistencies, it is not possible to correct them all. Caution has to be exercised in interpreting trend data.

9.1   MATERNITY CARE

Early and regular checkups by health professionals are very important in assessing the physical status of women during pregnancy and ensuring appropriate interventions during delivery. The 2003 GDHS obtained information from women on both the coverage of antenatal care and of key elements of the care received for the last birth during the five-year period before the survey.

9.1.1   Antenatal Care

Antenatal Care Coverage

Table 9.1 shows the percent distribution of women who had a live birth in the five years preceding the survey by the source of antenatal care for the most recent birth. In obtaining the information on source, interviewers recorded all persons a woman had seen for antenatal care. However, for cases where more than one person was seen, only the provider with the highest qualifications was considered in the analysis. Table 9.1 indicates that a relatively high percentage of women received antenatal care from a trained health professional, that is, a doctor, nurse, midwife or auxiliary midwife (21 percent from a doctor and 71 percent from a nurse/midwife). One percent of mothers received antenatal care from a traditional birth attendant (TBA) and 6 percent received no antenatal care.

Older women are less likely to receive antenatal care from a trained health professional than younger women. Women are also less likely to obtain care from a trained health professional for births of order six and higher. Ninety-eight percent of urban residents and 89 percent of rural residents got antenatal care from a trained heath professional. Urban residents are also more likely to receive antenatal care from doctors (34 percent) than rural residents (14 percent). Regional variations in antenatal care from a health professional is marked. Care from a doctor, for example, ranges from a high of 45 percent in Greater Accra to a low of 3 percent in the Upper East. In fact, less than 10 percent of women living in the three northern regions received antenatal care from a doctor, and one in six mothers in the Northern Region and one in seven mothers in the Upper East did not receive any antenatal care. Nevertheless, care from a nurse/midwife is encouragingly high in these regions

Table 9.1 Antenatal care

Fourth	24.1	71.2	2.2	2.1	0.3	100.0	474
Highest	50.6	47.6	0.0	0.6	1.2	100.0	433
Total	20.9	71.0	1.2	6.3	0.6	100.0	2,645
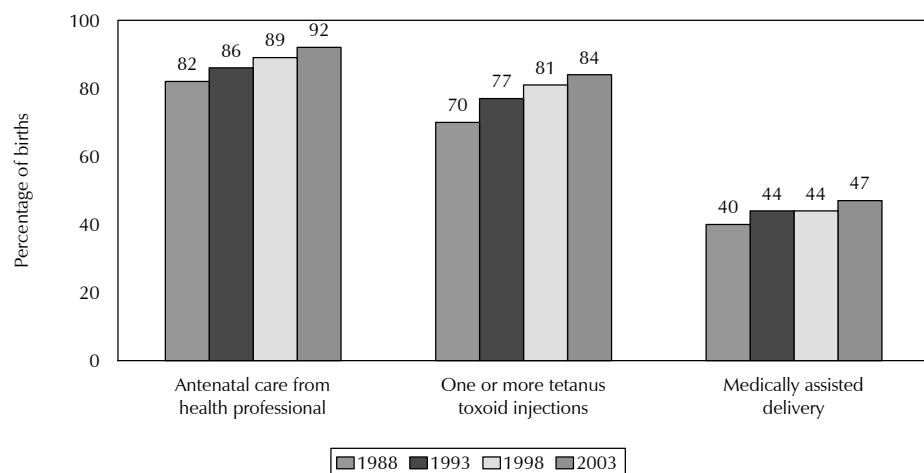

Note: If more than one source of ANC was mentioned, only the provider with the highest qualifications is considered in this tabulation.

Women's education is strongly associated with receipt of antenatal care from a health professional. As a woman's education increases, the likelihood that she will receive antenatal care from a health professional increases from 86 percent among women with no education to 100 percent among women

with at least some secondary. More than half (54 percent) of women with secondary and higher education saw a doctor for antenatal care compared with 11 percent of women with no education.

A comparison of the 2003 GDHS data with data from the three earlier GDHS surveys show that there has been an 11 percent improvement in the utilization of antenatal services in the past 15 years (Figure 9.1) from 82 percent of mothers receiving care for their most recent birth in the five-year period preceding the survey in 1988, to 92 percent in 2003.

Figure 9.1
Trends in Maternity Care Indicators
Ghana 1988-2003

Note: Data for 1988, 1993, and 1998 are with reference to births, whereas data for antenatal care
and tetanus toxoid for 2003 are with reference to women who had a live birth. The reference period
is five years preceding the survey except for 1993, which refers to the three years preceding the survey.   GDHS 1988-2003

Women who had a live birth in the five years preceding the survey were also asked about the source of antenatal care for their most recent birth. The majority of women (88 percent) seek antenatal care from a public source (data not shown). Government hospitals and clinics are by far the most common source providing antenatal care to 62 percent of women, followed by health centres, 25 percent. Twelve percent of women received antenatal care from a private facility, with most of them receiving care from private hospitals or clinics (9 percent).

Number and Timing of Antenatal Care Visits

Antenatal care can be more effective in preventing adverse pregnancy outcomes when it is sought early in the pregnancy and continued through to delivery. Obstetricians generally recommend that expectant mothers should begin antenatal attendance as early as possible in the first trimester. Monthly antenatal visits are recommended up to the seventh month of pregnancy, after which visits every two weeks are recommended up to the eighth month, when the visits should be weekly until delivery. If the first antenatal visit is made at the third month of pregnancy, this optimum schedule translates to a total of at least 12-13 visits during the duration of the pregnancy. The World Health Organisation (WHO) recommends a minimum of four visits per pregnancy. Early detection of problems in pregnancy leads to more timely referrals in case of complications and this is of particular importance in some remote regions of Ghana, where basic health services are few and present a challenge to the health care delivery system. Women who do not receive antenatal care during pregnancy are at a higher risk of obstetric emergencies and ad-

verse outcomes. In an effort to bridge the gap and provide health care as close to the family as possible, the District Health Management Teams have trained traditional birth attendants to recognise the danger signs during pregnancy and refer women early to health centres. This may explain the high percentage receiving antenatal care through facility-based health professionals. Table 9.2 provides the percentage distribution of women who had a live birth in the five years preceding the survey by the number of antenatal care (ANC) visits for the most recent birth, and by the timing of the first visit, according to residence.
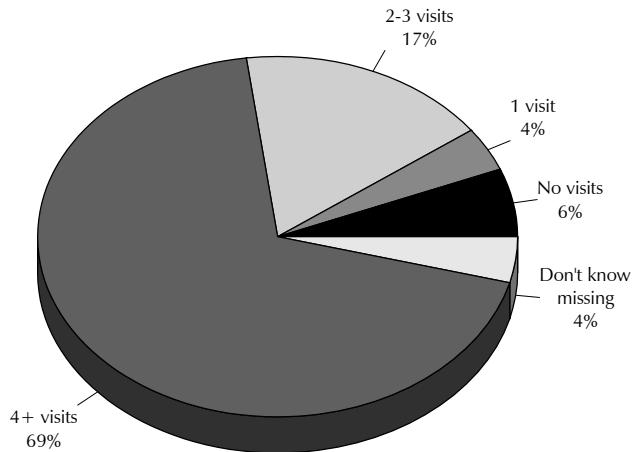

Most women (69 percent) have made at least four ANC visits for their most recent birth in the five years preceding the survey (Figure 9.2). Eighty-four percent of urban Ghanaians and 61 percent of rural Ghanaians report visiting antenatal clinics at least four times during their pregnancy. The median number of months pregnant at

Table 9.2 Number of antenatal care visits and timing of first visit

Percent distribution of women who had a live birth in the five years preceding the survey by number of antenatal care (ANC) visits for the most recent birth, and by the timing of the first visit according to residence, Ghana 2003

Number and timing of ANC visits	Residence		Total
	Urban	Rural	
Number of ANC visits			
None	1.2	9.2	6.3
1	0.9	5.7	4.0

Number of women	946	1,699	2,645

first visit among women who received antenatal care is 3.8 among urban residents and 4.2 among rural residents. More than half the women in urban areas and about two-fifths of women in rural areas make their first antenatal visit before their fourth month of pregnancy, while 34 percent of urban women and 35 percent of rural women make their first visit between the fourth and fifth month of pregnancy.

Figure 9.2 **Number of Antenatal Care Visits**

GDHS 2003

Components of Antenatal Care

Complications during pregnancy are an important cause of maternal and child morbidity and mortality. Detecting and monitoring these complications is a crucial component of safe motherhood. In order to gauge the quality of care received during pregnancy, the 2003 GDHS questioned women on whether ANC services included information about signs of pregnancy complications, blood pressure measurement, the testing of urine and blood samples, and the provision of iron supplements and anti-malarial prophylaxis tablets.

Some caution should be exercised in considering the information on the content of antenatal care. The information is dependent on a woman's understanding of the questions, for example, her understanding of what blood pressure measurement involves. It is also dependent on her recall of events during antenatal visits that may have taken place a number of years before the interview. Nonetheless, the results are useful in providing insights into the content of antenatal care for Ghanaian women.

Table 9.3 shows the percentage of women with a live birth in the five years preceding the survey who received antenatal care for the most recent birth, by content of antenatal care, and percentage of women with a live birth in the five years preceding the survey who received iron tablets or anti-malarial drugs for the most recent birth by background characteristics. As discussed earlier, antenatal care from a health professional is high in Ghana, and this may be reflected in the quality of care that expectant mothers receive. Three in five women (61 percent) are informed about the signs of complications during pregnancy. In addition, more than four in five women have their weight, blood pressure, and heights measured and have urine and blood samples taken. Although encouraging, programme managers need to ensure that all women coming for ANC services receive the full benefit of the services. Four in five women (whether or not they received ANC) are given iron tablets and three in five (58 percent) receive antimalarial drugs.

In general, the quality of antenatal care varies little by background characteristics, with the sharpest variation seen by education level and wealth status. Women with secondary education or higher (75 percent) are more likely than women with less education to be informed about signs of complications as are women in the highest wealth quintile (74 percent). Women with no education are also less likely to have a blood or urine sample taken or receive iron tablets than women with at least some education. For example, only 71 percent of women with no education received iron tablets compared with 85 percent of women with middle school education or higher.

Tetanus Toxoid Immunisation

An important component of antenatal care in Ghana is ensuring that pregnant women and children are adequately protected against tetanus. Tetanus toxoid injections are given during pregnancy for prevention of neonatal tetanus, an important cause of death among infants. Five doses given at specified periods provide lifetime protection. However, for full antenatal protection, a pregnant woman should receive two doses of tetanus toxoid. If a woman has been vaccinated during a previous pregnancy, then she may only require one dose during the current pregnancy.

Table 9.4 shows the percent distribution of women who had a live birth in the five years preceding the survey by number of tetanus toxoid injections received during the most recent pregnancy, according to background characteristics. The data show that half of women received at least two doses of tetanus toxoid, a third of women received only one tetanus toxoid injection, and 14 percent received none. There is little variation in tetanus toxoid coverage by age at birth and birth order. Urban women are three times as likely as rural women to have received tetanus toxoid injections.

Table 9.3 Components of antenatal care

Percentage of women with a live birth in the five years preceding the survey who received antenatal care for the most recent birth, by content of antenatal care, and percentage of women with a live birth in the five years preceding the survey who received iron tablets or anti-malarial drugs for the most recent birth, according to background characteristics, Ghana 2003

| Background characteristic | Women who received antenatal care | | | | | | | Received iron tablets | Received anti-malarial drugs | Number of women |

Coverage among mothers residing in the Northern, Upper West, and Upper East regions is lower than coverage in the other regions. Education is positively related to tetanus toxoid coverage — women with at least secondary education are six times more likely to have received tetanus toxoid injections as women with no education.

GDHS data show that there has been an improvement in tetanus toxoid coverage, for the most recent birth in the five years preceding the survey, from 70 percent in 1988 to 84 percent in 2003 (Figure 9.1).

9.1.2 Delivery Care

Place of Delivery

Traditionally, children in Ghana are delivered at home with the assistance of birth attendants or elderly women of the community. An important component of efforts to reduce the health risks of mothers and children is to increase the proportion of babies delivered under medical supervision. Proper medical attention and hygienic conditions during delivery can reduce the risk of complications and infections that can cause the death or serious illness of the mother and or the baby. Women interviewed in the 2003 GDHS were asked to report the place of birth of all children born in the five years before the survey.

Table 9.5 shows the percent distribution of live births in the five years preceding the survey by place of delivery according to background characteristics. Nationally, 46 percent of births are delivered in health facilities, with 36 percent in public health facilities and 9 percent in private health facilities. More than half of births (53 percent) occur at home. Mother's age at birth does not affect the place of delivery. First births and births of order two and three are more likely than higher order births to be delivered in a health facility. A child born in an urban area is two and a half times more likely to have been delivered at a health facility than a rural-born child. Four in five births in Greater Accra are delivered in a health facility compared with one in six births in the Northern region. As expected, a woman's education and wealth are strong determinants of institutional deliveries. For example, 89 percent of births to women with at least secondary education occurred in a health facility compared with 28 percent of births to women with no education. Eighty-nine percent of women in the highest wealth quintile had an institutional delivery compared with 19 percent of women in the lowest wealth quintile.

Antenatal care attendance has an impact on the proportion of births delivered in a health facility. Only 10 percent of births to women who did not receive antenatal care were delivered at a health facility compared with 59 percent of those to women with four or more antenatal visits.

Assistance at Delivery

The level of assistance a woman receives during the birth of her child also has important health consequences for both mother and child. Births delivered at home are more likely to be delivered without professional assistance, whereas births delivered at a health facility are more likely to be delivered by trained medical personnel. Table 9.6 shows the percent distribution of live births in the five years preceding the survey by the person who provided assistance during delivery according to background characteristics of the woman. The data show that medically trained providers assisted with 47 percent of deliveries, traditional birth attendants (TBA) assisted with 31 percent of deliveries, and relatives or friends attended 19 percent of deliveries.

First births are more likely to be delivered by a medically trained provider than those of second or higher order. Urban births are more likely (80 percent) to receive assistance from a medically trained provider compared with rural births (31 percent). Most births in Greater Accra (81 percent) receive assistance from medical personnel. Also, as seen with place of delivery, births to educated and wealthy women are more likely to be assisted at delivery by a medically trained professional.

Medically assisted deliveries continue to be low in Ghana, with less than 50 percent benefiting from professional delivery assistance over the past 15 years (Figure 9.1).

The 2003 GDHS included a question to determine if births in Ghana are registered with the government or local authority. The majority of births in the five years before the survey were not registered (54 percent), 44 percent were registered with the government or local authority, and the status was not known for 2 percent of births (data not shown).

Note: If the respondent mentioned more than one person attending during delivery, only the most qualified person is considered in this tabulation.

Delivery Characteristics

The 2003 GDHS enquired about some characteristics related to delivery. Table 9.7 shows the percentage of live births in the five years preceding the survey delivered by caesarean section and the percent distribution of the babies by birth weight and by mother's estimate of baby's size at birth, according to background characteristics. Only 4 percent of live births are delivered by caesarean section. This has not changed since 1998 (GSS and MI, 1999). Caesarean sections (C-sections) are highest among births to mothers in the oldest age cohort, first order births, urban births, births in Greater Accra, births to mothers who have at least secondary education, and births to mothers in the highest wealth quintile.

Table 9.7 Delivery characteristics

Percentage of live births in the five years preceding the survey delivered by caesarean section, and percent distribution by birth weight and by mother's estimate of baby's size at birth, according to background characteristics, Ghana 2003

Babies weighing less than 2.5 kilogrammes at birth are regarded as small or of low birth weight. Information on birth weight is known for only 28 percent of babies born in the five years preceding the survey. In the 2003 GDHS, 2 percent of all births weighed less than 2.5 kilogrammes at birth.

Since many respondents did not deliver in health facilities and would not have had their babies weighed at birth, women were also asked for their own subjective assessment of whether their babies were average or larger than average, smaller than average, or very small at birth. Although information of this type is subject to considerable error for individual births, in general, the proportion of births reported as very small or smaller than average has a high correlation to the prevalence of low birth weight. About one in five babies was assessed by their mothers as being very small or smaller than average. Births to mothers age less than 20 at birth, first order births, rural births, births in the Upper East Region, births to mothers with little or no education, and births to mothers in the lowest and middle wealth quintiles, are more likely to be reported as very small or smaller than average.

9.1.3 Postnatal Care

Another crucial component of safe motherhood is postnatal care. Postnatal check-ups provide an opportunity to assess and treat delivery complications and to counsel new mothers on how to care for themselves and their children. The timing of postnatal care is important. Since most maternal and neonatal deaths occur within two days of delivery, postnatal care should be received immediately following the birth, during this critical period. In the 2003 GDHS, questions on postnatal check-ups were asked only of women who had a non-institutional delivery, as it is assumed that women who delivered within a medical facility would have received care within the crucial first two days following delivery.

Table 9.8 shows the percent distribution of women who had a non-institutional live birth in the five years preceding the survey by timing of postnatal care for the most recent non-institutional birth, according to background characteristics. One in four women received postnatal care within two days of delivery, one in ten women received postnatal care 3-6 days after delivery, and one in eight received postnatal care 7-41 days after delivery. More than half of women who had a noninstitutional birth in the five years preceding the survey did not receive postnatal care.

There is little variation by mother's age at birth and urban-rural residence in postnatal care received; however, mothers of second and third order births, mothers with some education, and mothers in the middle and higher wealth quintiles are more likely than their counterparts to receive postnatal care. Wide regional variation also exists. Mothers residing in Greater Accra, Volta, Upper East, and Upper West regions are less likely than mothers residing in the other regions to have received postnatal care. The surprisingly low percentage in Greater Accra may be due to the small number of mothers with a noninstitutional delivery.

Table 9.8 Postnatal care by background characteristics

9.2   REPRODUCTIVE HEALTH CARE AND WOMEN'S STATUS

A woman's status has a direct impact on her health and health-seeking behaviour. Table 9.9 shows the percentage of woman with a live birth in the five years preceding the survey who received antenatal care from health professionals, the percentage of women who received postnatal care within the first two days of delivery, and the percentage of births for whom mothers received delivery care from a trained health professional, according to three measures of women's status: number of decisions in which a woman, either alone or jointly with others, has a final say; number of reasons women believe that a woman can refuse sex with her husband; and the number of reasons a woman believes that wife-beating is justified.

In general, women's status is positively related to women's reproductive health. However, information from the data gives a mixed picture. Table 9.9 shows that there is a clear positive relationship between qualified reproductive health care and women's attitude towards wife-beating. Women who believe that wife-beating is not justified for any reason are most likely to have received professional medical assistance for antenatal and delivery care and to have received postnatal care within the first two days of delivery. The percentage of women who receive reproductive health care from medical professionals declines as the number of reasons women believe wife-beating is justified increases. Table 9.9 also shows that women who have the final say in all five household decisionmaking processes are most likely to have received maternity care from a health professional. However, the differences are less obvious for antena-

Women's status indicator	Percentage of women who received antenatal care from doctor, nurse/midwife or auxiliary midwife	Percentage of women who received postnatal care within first two days of delivery[1]	Number of women	Percentage of births for which mother received delivery care from doctor, nurse/ midwife or auxiliary midwife	Number of births

Table 9.9 Reproductive health care by women's status

Percentage of women with a live birth in the five years preceding the survey who received antenatal and postnatal care from a health professional for the most recent birth, and percentage of births in the five years preceding the survey for which mothers received professional delivery care, by women's status indicators, Ghana 2003

[1] Includes mothers who delivered in a health facility
[2] Either by herself or jointly with others

tal care than for delivery and postnatal care. In addition, this relationship does not hold true for all the subcategories of decisionmaking. For example, a higher percentage of women who have no say in any of the five major household decisions have received medical reproductive health care than their counterparts who have a say in one to four of the five decisions. This same pattern is also observed for women who believe that a woman is justified in refusing sex with her husband.

9.3 CHILD HEALTH

9.3.1 Vaccination of Children

The 2003 GDHS collected information on immunisation coverage for all children born in the five years before the survey. The Government of Ghana has adopted the World Health Organisation (WHO) and UNICEF guidelines for vaccinating children. According to these guidelines, to be considered fully vaccinated, a child should receive the following vaccinations: one dose each of BCG and measles, three doses of the polio vaccine, and three doses of DPT. In addition, in Ghana a vaccine against yellow fever is also recommended for children. BCG, which protects against tuberculosis, should be given at birth or at first clinical contact. DPT protects against diphtheria, pertussis (whooping cough), and tetanus. A dose of polio vaccine is given at birth (Polio 0) or within 13 days of birth. DPT and polio vaccine guidelines require three vaccinations at approximately 6, 10, and 14 weeks of age. The measles and yellow fever vaccines should be given at nine months of age. Currently, the pentavalent vaccine "DPT/HepB/HiB", introduced in 2002, has replaced the DPT vaccine. This vaccine contains in addition to DPT, the hepatitis B vaccine and a vaccine against *Haemophilus* influenza type B. It is recommended that children receive the complete schedule of vaccinations before 12 months of age.

In the GDHS, information on vaccination coverage was obtained in two ways—from health cards and from mother's verbal reports. All mothers were asked to show the interviewer the health cards on which the child's immunisations are recorded. If the card was available, the interviewer copied the dates on which each vaccination was received. If a vaccination was not recorded on the card, the mother was asked to recall whether that particular vaccination had been given. If the mother was not able to present a card for a child at all, she was asked to recall whether the child had received BCG, polio, DPT, measles, and yellow fever vaccinations. If she recalled that the child had received the polio or DPT vaccines, she was asked about the number of doses that the child received.

The data presented here are for children age 12-23 months, the youngest cohort of children who have reached the age by which they should be fully vaccinated, and are restricted to children who were alive at the time of the survey. Table 9.10 shows the percentage of children age 12-23 months who received specific vaccines at any time before the survey by source of information. Sixty-nine percent of Ghanaian children age 12-23 months are fully immunised, while 5 percent received no vaccinations[1] (Figure 9.3). Fifty-eight percent of children 12-23 months were fully vaccinated by 12 months of age.

---

[1] Data for polio vaccinations were adjusted for a likely underreporting. It appeared that for some children who did not receive polio at birth, interviewers may have mistakenly written the date polio 1 was given in the space for recording the date of polio 0. To correct for any such errors, the total number of doses of DPT and polio was checked, since the two vaccines are usually given at the same time. For children reported as having received all three doses of DPT and polio 0, polio 1, and polio 2 only, it was assumed that polio 0 was in fact polio 1, polio 1 was in fact polio 2, and polio 2 was in fact polio 3.

Table 9.10 Vaccinations by source of information

[1] Polio 0 is the polio vaccination given at birth
[2] BCG, measles and three doses each of DPT (DPT/HepB/HiB) and polio vaccine (excluding polio vaccine given at birth)
[3] For children whose information was based on the mother's report, the proportion of vaccinations given during the first year of life was assumed to be the same as for children with a written record of vaccination

Figure 9.3
Percentage of Children Age 12-23 Months with Specific Vaccinations

Note: Based on health cards and mothers' reports
[1] BCG, measles, and three doses each of DPT and polio vaccine (excluding polio 0)   GDHS 2003
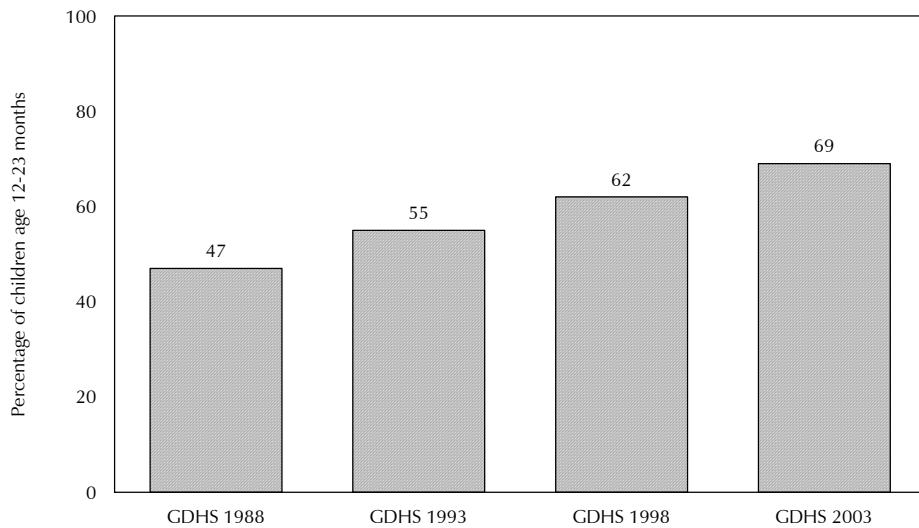

Nine in ten children received the BCG and first dose of DPT and polio vaccines at some time before the survey. While the coverage for the first dose of DPT and polio is high, coverage declines for subsequent doses of DPT and polio, with only about 80 percent of children receiving the recommended three doses of these vaccines. The drop-out rate represents the proportion of children who receive the first dose of a vaccine but do not go on to get the third dose. Dropout rates are 12 percent and 15 percent for DPT and polio, respectively. This is an improvement from 1998 when drop-out rates for DPT and polio were 19 percent and 22 percent, respectively (GSS and MI, 1999). Eighty-three percent of children received the measles vaccine and 77 percent have been vaccinated against yellow fever. Ideally, measles and yellow fever should be given on the same day and the difference in vaccination coverage poses a challenge for

health professionals. The percentage of children age 12-23 months who have been fully vaccinated has increased over the past fifteen years, from 47 percent in 1988 (GSS and IRD, 1989), to 69 percent in 2003 (Figure 9.4).

Figure 9.4
Trends in Vaccination Coverage, Ghana 1988-2003

Note: Children age 12-23 months fully vaccinated, i.e., have received BCG, measles, and three doses of DPT and polio (excluding polio 0).

GDHS 1988-2003

Table 9.11 shows the percentage of children age 12-23 months who received specific vaccines at any time before the survey (according to a vaccination card or the mother's report), and the percentage with a vaccination card by background characteristics.

The gender and birth order of the child has little effect on vaccination status. Urban children are more likely than their rural counterparts to be fully immunised. Apart from the Northern region, where less than half of the children are fully immunised, at least three in five children in each of the other regions are fully immunised. Children of women with no education were less likely (57 percent) to be fully immunised than children of educated mothers. Similarly, children in households in the lowest wealth quintile (54 percent) are least likely to be fully immunised.

Table 9.12 provides the percentage of children age 12-59 months at the time of the survey who received specific vaccines by 12 months of age, and the percentage with a vaccination card, by current age of child. Half of the children received all vaccines by 12 months of age. Children in the older cohort (48-59 months) were less likely (42 percent) to have received all their vaccines compared with those age 12-23 months (58 percent). This pattern was consistent for each vaccine but more marked when all the vaccines are considered together. This corroborates the trend towards higher immunisation coverage in 2003 than in 1998.

Table 9.11 Vaccinations by background characteristics

[1] Polio 0 is the polio vaccination given at birth
[2] BCG, measles and three doses each of DPT and polio vaccine (excluding polio vaccine given at birth)

Table 9.12 Vaccinations in first year of life

Percentage of children age 12-59 at the time of the survey who received specific vaccines by 12 months of age, and percentage with a vaccination card, by current age of child, Ghana 2003

Current age of child in months	BCG	DPT			Polio[1]				Measles	All[2]	Yellow fever	No vacci-nations	Percentage with a vaccination card seen	Number of children
		1	2	3	0	1	2	3						
12-23	90.0	90.0	85.3	76.9	53.6	92.2	87.2	75.9	68.8	58.0	58.5	6.1	83.0	695
24-35	86.6	87.4	82.0	72.6	46.1	91.1	86.2	71.0	67.8	52.2	51.9	7.6	73.3	649
36-47	86.1	85.2	78.1	69.0	45.8	88.4	80.9	65.6	61.0	46.3	52.1	10.1	64.9	695
48-59	84.4	82.8	76.5	65.3	42.6	87.8	79.7	63.5	59.9	41.7	50.5	9.9	60.2	612
Total	86.9	86.6	80.8	71.3	47.2	90.1	83.8	69.4	64.9	50.0	53.9	8.3	70.6	2,652

Note: Information was obtained from the vaccination card or if there was no written record, from the mother. For children whose information was based on the mother's report, the proportion of vaccinations given during the first year of life was assumed to be the same as for children with a written record of vaccinations.
[1] Polio 0 is the polio vaccination given at birth
[2] BCG, measles, and three doses each of DPT and polio vaccine (excluding polio vaccine given at birth)

9.3.2 Acute Respiratory Infections

Pneumonia and other respiratory tract infections are leading causes of death among young children in Ghana. In cases of pneumonia, early diagnosis and treatment with antibiotics can prevent a large proportion of deaths due to acute respiratory infections (ARI). The prevalence of ARI in the 2003 GDHS was estimated by asking mothers whether their children under age five had been ill with a cough accompanied by short, rapid breathing in the two weeks preceding the survey. These symptoms, though compatible with pneumonia, are subjective (i.e., mother's perception of illness) and not validated by a medical examination. Table 9.13 shows the percentage of children under five years who had a cough accompanied by short rapid breathing (symptoms of ARI) and the percentage of children with symptoms of ARI taken to a health facility or provider.

Mothers reported that 10 percent of children under five had symptoms of ARI in the two weeks prior to the survey. Of these, 44 percent were taken to a health facility or provider. Differentials in the prevalence of ARI by background characteristics are minimal. However, it is worthwhile to note that symptoms of ARI are particularly high among children age 6-23 months and among children living in the Volta region.

Treatment patterns vary by background characteristics. Children age 12-35 months, urban children, and children of mothers with middle/JSS level of education are more likely than other children to be taken to a health provider for treatment. Differentials by region are hard to interpret due to the small number of cases.

Table 9.13 Prevalence and treatment of symptoms of ARI

Percentage of children under five years who had a cough accompanied by short, rapid breathing (symptoms of acute respiratory infection (ARI)), and among children who had symptoms of ARI, the percentage for whom treatment was sought from a health facility or provider, by background characteristics, Ghana 2003

9.3.3 Diarrhoeal Diseases

Dehydration caused by severe diarrhoea is a major cause of morbidity and mortality among young children in Ghana. Exposure to diarrhoeal-causing agents is frequently related to use of contaminated water and unhygienic practices related to food preparation, hand-washing, and excreta disposal. For health purposes, it is essential that each household have a specific area designated for hand washing where water, soap, ash, or other cleansing agent as well as a basin for containing clean water are present. This is more likely to ensure regular hand-washing.

Hand-washing

In the GDHS, respondents were asked where they usually washed their hands. Interviewers were then asked to observe for various hand-washing items for those households that mentioned having an area 'designated,' or set aside specifically for hand-washing 'in the dwelling, yard or plot.' In each household, interviewers were instructed to circle the following items as present or absent: water or a tap in the designated location where members of the household usually washed their hands, cleansing agent such as soap or ash, and a basin to hold clean water. Table 9.14 shows the percentage of households with hand-washing materials in a designated area within the dwelling, yard, or plot by background characteristics. It is surprising to note that 67 percent of households did not have any hand-washing items in the designated place for hand-washing. This may not mean that hand-washing items are uncommon in Ghana, but may in part be a reflection of the absence of a designated place for hand-washing. Moreover, in some parts of the country, many households live in compound houses where washing areas may be shared between several households, and personal use items such as soap, may not be kept at the designated washing bay for others to use. Twenty-nine percent of households had water or a tap, 14 percent had soap, ash, or other cleansing agent, and 16 percent had a basin in the designated area for hand-washing. Only 8 percent of households had all three hand-washing materials in the designated area for hand-washing within the dwelling, yard, or plot.

Households in urban areas, those in Greater Accra, those with piped water or with a water source within the dwelling, and households in the highest wealth quintile are more likely than other households to have all three hand-washing materials in a place designated for hand-washing.

Table 9.14 Hand-washing materials in household

Percentage of households with hand-washing materials in a designated place within dwelling/yard/plot, by background characteristics, Ghana 2003

Total includes 4 cases with missing information on toilet facilities.

More than half of mothers (55 percent) report that their child's stool is contained in the toilet or latrine or buried in the yard. Thirty-six percent of mothers report that their child's stool is uncontained, that is, thrown outside the dwelling or yard, rinsed away, or not disposed of. Seven percent of mothers reported using diapers. Children's stools are more likely to be contained in urban than in rural areas, in the Eastern Region, by highly educated mothers, in households with improved latrines or flush toilets, and among mothers in the highest wealth quintile.

Incidence of Diarrhoea

In the 2003 GDHS, mothers were asked whether any of their children under five years of age had diarrhoea at any time during the two-week period prior to the survey. If any child had diarrhoea, the

mother was asked about feeding practices during the diarrhoeal episode and about what actions were taken to treat the diarrhoea. Since the prevalence of diarrhoea varies seasonally, the results, which only pertain to the period of fieldwork from late July to late October, should be interpreted with caution. Table 9.16 shows that 15 percent of children under five years had diarrhoea in the two weeks preceding the survey. Not surprisingly, very young children are least likely to have had diarrhoea, presumably because most of them are exclusively breastfed and hence less exposed to contaminated food. Children residing in the Upper East and Upper West regions have a much higher prevalence of diarrhoea than children in the other regions. Prevalence of diarrhoea is lowest among children of highly educated mothers. Not surprisingly, diarrhoea prevalence is lowest among children who live in households that have all three hand-washing materials, households that have piped water, and households that are in the wealthiest quintile.

Use of Oral Rehydration Therapy

A simple and effective response to dehydration associated with diarrhoea is a prompt increase in the child's fluid intake through food and oral rehydration therapy (ORT). ORT may include the use of a solution prepared from commercially produced packets of oral rehydration salts (ORS) or a homemade mixture usually prepared from sugar, salt, and water (recommended home fluids, RHF). Table 9.17 shows the percentage of mothers with births in the five years preceding the survey who know about ORS packets for treatment of diarrhoea, by background characteristics.

Ninety percent of mothers with births in the five years preceding the survey know about ORS. Younger mothers are slightly less likely to know about ORS than older mothers. Knowledge among urban women is higher than among rural women. Knowledge of ORS is lowest among young mothers in the Upper West Region, among mothers with no education, and among mothers in the lowest wealth quintile.

Note: An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed. Figures in parentheses are based on 25-49 unweighted cases. ORT includes solution prepared from oral rehydration salt (ORS) packets, recommended home fluids (RHF), or increased fluids.
[1] Excludes pharmacy, shop and traditional practitioner

recommended home fluids (RHF), and 40 percent were given increased fluids. Overall, 63 percent received ORS, RHF, or increased fluids. One-third of children with diarrhoea were given pills or syrup, 1 percent received injections, less than 1 percent received intravenous medication, and 12 percent were given home remedies. One in seven children with diarrhoea were given no treatment at all.

Children age 6-11 months are slightly more likely to be taken to a health facility for treatment (32 percent) than those over one year (22-26 percent). Male children (27 percent) are slightly more likely than female children (23 percent) to be taken to a provider for treatment of diarrhoea. Children of women in the highest wealth index were also more likely (42 percent) to be taken to a health provider than children from poorer households. Very young children (6-11 months) and older children (48-59 months) are less likely than other children to receive ORT. Rural children and children in the lowest wealth quintile are also less likely to receive ORT.

Feeding Practices

Mothers are encouraged to continue feeding their children normally when they suffer from diarrhoea and to increase the amount of fluids given. These practices help to reduce the likelihood of dehydration and also minimise the adverse consequences of diarrhoea on the child's nutritional status. Table 9.19 presents data on the percent distribution of children under five years who had diarrhoea in the two weeks preceding the survey by the amount of liquids and food offered compared with normal practice. Most children are given either the same amount of fluids (32 percent) or more fluids than usual (40 percent) when they have diarrhoea. Fourteen percent of children are given somewhat less fluids than usual, while 12 percent are given much less. One percent of children receive no fluids.

Twenty-seven percent of children are offered the same amount of food and 6 percent are offered more food than usual. Thirty percent receive somewhat less food and 26 percent receive much less food than usual, while 7 percent receive no food at all.

Men are beginning to play a more important role in child caring. In order to ascertain men's knowledge about feeding practices, the 2003 GDHS asked all men about what they should do when a child had diarrhoea. Forty percent of men mentioned that they would give a child with diarrhoea more fluids to drink, while 13 percent mentioned

Table 9.19 Feeding practices during diarrhoea

Total	100.0
Number of children	509

that they would give the same amount of fluid to drink (data not shown). More than a third of men (35 percent) stated that they would give a child less than usual to drink in the event of diarrhoea.

9.4   CHILD HEALTH CARE AND WOMEN'S STATUS

A woman's status could have an impact on the level of health care her child receives. Table 9.20 shows the percentage of children age 12-23 months who were fully vaccinated and the percentage of children under five years who were ill with a fever and/or who had symptoms of ARI and/or diarrhoea in the two weeks preceding the survey who were taken to a health provider for treatment, by women's status indicators.

Table 9.20 Children's health care by women's status

Percentage of children age 12-23 months who were fully vaccinated, and percentage of children under five years who were ill with a fever, symptoms of ARI and/or diarrhoea, in the two weeks preceding the survey taken to a health provider for treatment, by women's status indicators, Ghana 2003

Women's status indicator	Percentage of children 12-23 months fully vaccinated[1]	Number of children	Percentage of children with fever and/or symptoms of ARI taken to health provider[2]	Number of children	Percentage of children with diarrhoea taken to a health provider[2]	Number of children
Number of decisions in which woman has final say[3]						
0	58.5	136	47.6	175	32.0	114
1-2	68.9	157	44.8	187	24.7	125
3-4	75.8	132	44.2	149	17.7	96
5	72.0	270	43.2	328	26.2	175
Number of reasons to refuse sex with husband						
0	65.3	54	48.5	55	28.3	35
1-2	67.0	95	37.0	129	26.2	74
3-4	70.2	547	45.8	655	25.1	400
Number of reasons wife-beating is justified						
0	73.9	323	48.9	385	23.0	211
1-2	79.3	166	41.0	196	24.1	119
3-4	55.9	138	41.0	200	25.9	116
5	51.5	68	41.1	57	35.9	62
Total	69.4	695	44.6	839	25.5	509

[1] Those who have received BCG, measles, and three doses each of DPT and polio vaccine (excluding polio vaccine given at birth)
[2] Excludes pharmacy, shop, and traditional practitioner
[3] Either by herself or jointly with others

The relationship between child health care and women's status is mixed. The data show that the percentage of children 12-23 months fully vaccinated is higher among children of mothers who have a higher status as measured by all three measures of women's status. For example, a higher percentage of children of mothers who have a greater say in household decisionmaking (3-5 decisions) are fully immunised than children of mothers who have little or no say (72-75 and 59 percent, respectively). Children of mothers who believe that wife-beating is not justified for any reason at all are also more likely than their counterparts to be taken to a health care provider for treatment of fever and/or ARI. However, there is no clear relationship between the other two women's status indicators and the care children receive for childhood illnesses.

9.5   WOMEN'S PERCEPTIONS OF PROBLEMS IN OBTAINING HEALTH CARE

The 2003 GDHS included a series of questions aimed at obtaining information on the problems women perceive as barriers to accessing health care for themselves. This information is particularly important in understanding and addressing the barriers women may face in seeking care in general. To ob-

tain this information, all GDHS respondents were asked whether each of the following factors would pose a big problem in obtaining medical advice or treatment when they are sick: knowing where to go; getting permission to go; getting money for treatment; distance to the health facility; having to take transport; not wanting to go alone; and concern that there may not be a female provider. Table 9.21 shows the percentage of women who reported that they have big problems in accessing health care for themselves when they are sick, by type of problem and background characteristics.

Clearly, women have problems in accessing health care services, with 68 percent of all women citing at least one of the specified problems. The majority of women said that difficulty in getting money for treatment was a big problem (55 percent), followed by problems with transport and distance to a health facility (33 percent each). Sixteen percent of women were concerned that there may not be a female health provider. Few women (about one in ten) cited knowing where to go for treatment or getting permission to go as big problems in accessing health care for themselves.

Women who have five or more children, divorced, separated or widowed women, rural women, women residing in the Upper East Region, women with no education, women who work but not for cash, and women who fall in the lowest wealth quintile are more likely to mention a problem in accessing health care than other women.

9.6   USE OF SMOKING TOBACCO

Smoking has a negative effect on the health of a person. Women and men interviewed in the 2003 GDHS were asked about their smoking habits. The data show that very few women in Ghana (less than 1 percent) smoke (data not shown).

Table 9.22 indicates the percentage of men who smoke cigarettes or tobacco and the percent distribution of cigarette smokers by number of cigarettes smoked in the preceding 24 hours, according to background characteristics.

Smoking is not common in Ghana. Only 9 percent of men smoke cigarettes, a negligible percent smoke a pipe, and 2 percent use other tobacco products. Cigarette smoking is more common among older men (16 percent), men in rural areas (11 percent), men living in the Northern Region (18 percent), men with no education (20 percent), and men in the lowest wealth quintile (15 percent). The majority (78 percent) of men smoke 1-5 cigarettes a day. Heavy smoking (six or more cigarettes a day) is concentrated in Greater Accra, Ashanti, and Northern regions, and among wealthier men (fourth and highest wealth quintiles).

Table 9.21 Problems in accessing health care

Percentage of women who reported they have big problems in accessing health care for themselves when they are sick, by type of problem and background characteristics, Ghana 2003

	Problems in accessing health care

NUTRITION

10

Malnutrition plays an important role in the health and welfare of children and women in Ghana. Poor nutrition results in morbidity, mortality, poor education, and fewer opportunities for economic development. Poor education, low socio-economic status, and high fertility are factors that may influence the nutritional status of an individual. In Ghana, children under five years and women of reproductive age are the most vulnerable. Economic evidence also suggests that life expectancy is directly related to poverty and nutrition (Sachs, 1999). Adequate food and sound nutrition are essential to good health. They are crucial not only for human survival, but also for prevention of and recovery from illness.

The 2003 GDHS collected data from respondents in order to evaluate the nutritional status of women and young children. For infants and young children, this included information on breastfeeding and complementary feeding. For micronutrients like iron, vitamin A, and iodine, information was collected on intake levels from supplementation and food. Anthropometric measurements (height and weight) were taken for women 15-49 years and children under age five to determine their nutritional status.

10.1 BREASTFEEDING

Appropriate feeding practices are of fundamental importance for the survival, growth, development, health, and nutrition of infants and children and for the well being of mothers. Feeding practices are one of the underlying determinants of children's nutritional status, which in turn influence the risk of illness and ultimately death. Breastfeeding benefits depend on the length of time a child is breastfed, and the frequency and intensity of breastfeeding. Breastfeeding also affects the mother in other ways. The physiological suppression of fertility as a result of intensive breastfeeding influences the length of the interval between pregnancies.

10.1.1 Initiation of Breastfeeding

Breastfeeding is sufficient and beneficial for infant nutrition in the first six months of life. Early initiation of breastfeeding (breastfeeding within one hour) facilitates the newborn's innate sucking reflex, which helps to stimulate breast milk production and provides all of the nutritional requirements of a young infant (Righard and Alade, 1990). The high concentration of antibodies in colostrum, the first yellowish, highly nutritious milk that is present right after delivery, protects the child from infection before the child's immune system has matured. Early initiation also encourages the bond between mother and baby and helps to maintain the baby's body temperature. Breastfeeding also helps the uterus to retract, hence reducing postpartum blood loss of the mother. Prelacteal feeding (giving something other than breast milk in the first three days of life) is generally discouraged since it may inhibit breastfeeding and expose the newborn infant to illness.

The Baby Friendly Hospital Initiative (BFHI) started in health facilities in Ghana in 1993. This may have had an impact on breastfeeding initiation and the giving of prelacteal feeds among children of mothers assisted at delivery by medically trained health professionals and those delivered in a health facility.

Table 10.1 shows the percentage of children born in the five years preceding the survey who were ever breastfed and among children ever breastfed, the proportion who started breastfeeding within one

Table 10.1 Initial breastfeeding

Percentage of children born in the five years preceding the survey who were ever breastfed, and among children ever breastfed, percentage who started breastfeeding within one hour and within one day of birth and percentage who received a prelacteal feed, by background characteristics, Ghana 2003

Background characteristic	All children		Children ever breastfed

Note: Table is based on all births whether the children are living or dead at the time of interview. Total includes 27 children with missing information on assistance at delivery, 24 persons with missing information on place of delivery, and 14 persons with 'other' place of delivery, who are not shown separately. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.
[1] Includes children who started breastfeeding within one hour of birth
[2] Children given something other than breast milk during the first three days of life before the mother started breastfeeding regularly
[3] Doctor, nurse/midwife, or auxiliary midwife

hour and within one day of birth, and those who received a prelacteal feed. The data indicate that almost all (97 percent) Ghanaian children are breastfed for some period of time. Forty-six percent of infants were put to the breast within one hour of birth, and 75 percent started breastfeeding within the first day. The data from 2003 can be compared with similar data collected five years ago. The data show that over the past five years, there was little difference in the percentage of children ever breastfed. However, the percentage breastfed within one hour of birth and one day of birth for children born in the five years preceding the survey (46 and 75 percent, respectively) is noticeably higher than the 1998 levels (25 and 54 percent, respectively) (GSS and MI, 1999).

There are no marked differences in the proportion of children ever breastfed by background characteristics. Children of mothers assisted at delivery by medically trained health professionals (doctors, nurse/midwives, or auxiliary nurses) and children delivered in a health facility are more likely to be breastfed immediately after birth or within one day of birth.

Initiation of breastfeeding varies among regions. The proportion of infants that are breastfed within one hour of birth ranges from 14 percent in the Central Region to 86 percent in the Upper East Region. The Western Region has the lowest percentage of children who started breastfeeding within one day of birth (67 percent), while the Upper East Region has the highest (93 percent).

Prelacteal feeding, something other than breast milk given to newborns prior to the regular flow of breastmilk, is not widely practised in Ghana. Only 20 percent of children born in the five years preceding the survey received a prelacteal feed. Prelacteal feeding is more widely practiced in rural areas (22 percent) than urban areas (14 percent). The Western Region (29 percent) has the highest reported percentage of prelacteal feeding. Children of mothers assisted at delivery by medically trained health professionals have a lower reported rate of receiving prelacteal feeds (14 percent). Women who delivered at home have higher reported rates of prelacteal feeding (25 percent) than those who delivered in a health facility (14 percent). The practice decreases from 24 percent among children of women in the lowest wealth quintile to 10 percent among children of women in the highest wealth quintile.

10.1.2 Age Pattern of Breastfeeding

Breast milk is safe, convenient, uncontaminated, and contains all the nutrients needed by the baby in the first six months of life. In Ghana, all women are encouraged to breastfeed their infants exclusively for the first six months and then complement the breastfeeding with nutritious foods for at least two years. Breast milk provides protection against infection through the mother's antibodies. Supplementing breast milk before 6 months is unnecessary and is strongly discouraged because of the likelihood of contamination, the unaffordability of breast milk substitutes, and the resulting increased risk of diarrhoeal disease. The early introduction of liquids and solids reduces breast milk output because the production and release of milk is influenced by the frequency and intensity of suckling. Breastfeeding remains the best nutrition even for infants of HIV-positive mothers and mothers whose HIV status is unknown, as it provides resistance to opportunistic diseases.

Table 10.2 shows the percent distribution of youngest children under three years living with the mother by breastfeeding status and percentage of children under three years using a bottle with a nipple, according to age in months. Based on information about feeding practices in the 24 hours preceding the survey, almost all children are breastfed for at least one year, with only 4 percent of children aged 12-15 months who are not breastfed. By age 16-19 months, 14 percent of children are no longer breastfeeding. Breastfeeding decreases rapidly late in the second year of life, and by 32-35 months of age, virtually all children (94 percent) are weaned.

Table 10.2 Breastfeeding status by age

Percent distribution of youngest children under three years living with the mother by breastfeeding status and percentage of children under three years using a bottle with a nipple, according to age in months, Ghana 2003

| | | | Breastfeeding and consuming: | | | | | | Percentage | |

6-9	0.4	9.6	22.8	2.4	2.7	62.2	100.0	239	12.2	241
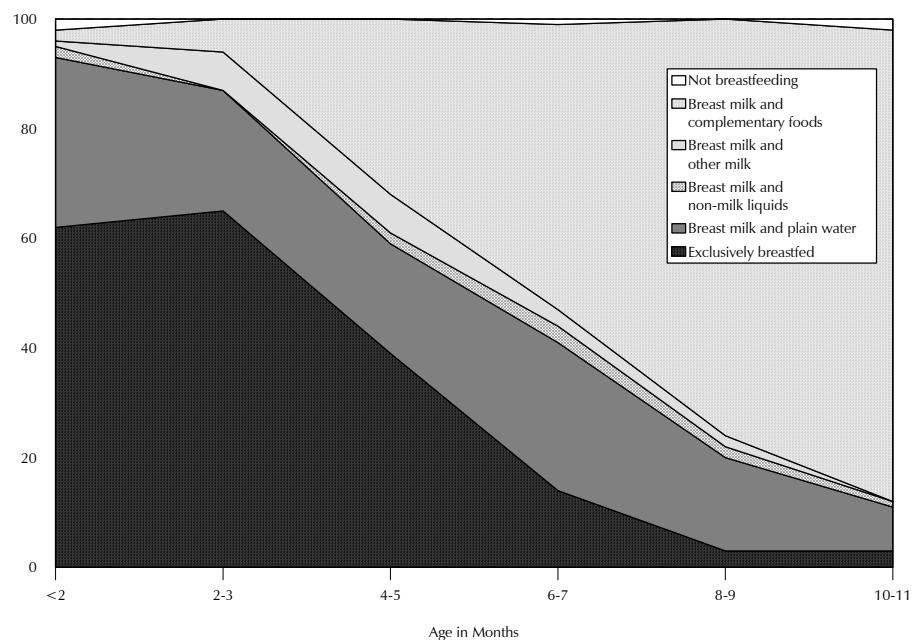

Note: Breastfeeding status refers to a "24-hour" period (yesterday and last night). Children classified as *breastfeeding and consuming plain water only* consume no supplements. The categories of not breastfeeding, exclusively breastfed, breastfeeding and consuming plain water, water-based liquids/juice, other milk, and complementary foods (solids and semi-solids) are hierarchical and mutually exclusive, and their percentages add to 100 percent. Thus children who receive breast milk and water-based liquids and who do not receive complementary foods are classified in the water-based liquid category even though they may also get plain water. Any children who get complementary food are classified in that category as long as they are breastfeeding as well.
[1] Based on all children under three years

Despite the high breastfeeding prevalence (97 percent) in Ghana, the majority of infants are not fed in compliance with the WHO/UNICEF recommendations (World Health Assembly, 2001). These recommendations call for a period of exclusive breastfeeding for 6 months and the introduction of complementary foods after the age of 6 months. Fifty-three percent of children under 6 months of age are exclusively breastfed in Ghana. This is a slight increase over the proportion reported in the 1998 GDHS (GSS and MI, 1999).

Exclusive breastfeeding drops sharply from 65 percent at age 2-3 months to 39 percent at age 4-5 months (Figure 10.1). Six percent of children age 2-3 months and 32 percent of children age 4-5 months are receiving complementary foods in addition to breast milk. This indicates that there are many infants who are at risk of being exposed to bacterial contamination and poor quality foods, even if they started out well with early initiation of breastfeeding. The duration of paid maternity leave in Ghana is 12 weeks; hence, a majority of women return to work when their children are three months old. This may account for the sharp decline in exclusive breastfeeding rates between 2-3 months and 4-5 months.

Figure 10.1 Breastfeeding Practices by Age, Ghana 2003

The use of a feeding bottle with a nipple is discouraged in Ghana. HIV-positive mothers are told not to use feeding bottles even when they choose to use formula as their feeding option. The use of a bottle with a nipple, regardless of the contents (formula or any other liquid), requires hygienic handling. As a result of inadequate and insufficient cleaning and ease of recontamination after cleaning, the nipple may house disease-causing agents transferable to the baby. Table 10.2 indicates that 12 percent of children under six months and the same proportion of children age 6-9 months are given a feeding bottle with a nipple. Bottle-feeding reaches its peak (15 percent) at age 4-5 months. The percentage of children who are bottle-fed declines to 5 percent by the age of two years. It however increases slightly after that to 6 percent by 28 months. It is assumed that by two years most children are eating solid foods, which does not require feeding by bottle. The percentage of young children bottle-fed has declined markedly over the past five years. For example, bottle-feeding at age 4-5 months has declined from 26 percent in 1998 (GSS and MI, 1999) to 15 percent in 2003.

Table 10.3 presents information on the median duration of any breastfeeding, exclusive breastfeeding, and predominant breastfeeding among children born in the three years preceding the survey, the percentage of breastfeeding children under six months living with the mother who were breastfed six or more times in the 24 hours preceding the survey, and the mean number of feeds (day and night), by background characteristics.

The median duration of any breastfeeding in Ghana is 23 months. Regional differences in breastfeeding prevalence are minimal, with the longest duration being 28 months in the Northern Region and the lowest (19 months) in Greater Accra. The median duration of exclusive breastfeeeding is 2 months and the median duration of predominant breastfeeding is 5 months. Children are considered predominantly breastfed when they are either exclusively breastfed or receive breast milk and plain water, water-based liquids, and/or juice only (excluding other milk and solids).

Frequent breastfeeding improves the production of breast milk. It is also a benefit for some mothers who breastfeed exclusively as it delays the return of fertility.

Table 10.3 indicates that almost all breastfed children under 6 months (97 percent) are breastfed six or more times in the past 24 hours, with an average of 7 daytime feeds and 5 nighttime feeds.

Table 10.3 Median duration and frequency of breastfeeding

Median duration of any breastfeeding, exclusive breastfeeding, and predominant breastfeeding among children born in the three years preceding the survey, percentage of breastfeeding children under six months living with the mother who were breastfed six or more times in the 24 hours preceding the survey, and mean number of feeds (day/night), by background characteristics, Ghana 2003

| Background characteristic | Median duration (months) of breastfeeding[1] | | | | Breastfeeding children under six months[2] | | | |

Note: Median and mean durations are based on current status. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed. Percentages in parentheses are based on 25-49 unweighted cases.
 na = Not applicable
[1] It is assumed that non-last-born children or last born child not living with the mother are not currently breastfeeding
[2] Excludes children who do not have a valid answer on the number of times breastfed
[3] Either exclusively breastfed or received breast milk and plain water, water-based liquids, and/or juice only (excludes other milk)

Although the median duration of breastfeeding is slightly longer in the rural areas (23 months) than in the urban areas (20 months), exclusive breastfeeding is somewhat shorter in rural areas (1 month) than in urban areas (4 months). Exclusive breastfeeding rates increase with increases in mother's level of education and wealth quintile.

10.2   COMPLEMENTARY FEEDING

10.2.1 Types of Complementary Foods

In line with the WHO/UNICEF global strategy on infant and young child feeding, the Ghana Health Service recommends 6 months as the optimal age to introduce complementary foods. This is because after 6 months of age, breast milk alone is not sufficient to meet all the nutritional requirements of the infant. The period after 6 months of age is a crucial time for children because they are being introduced to the family diet, and a number of issues come into force. These include income, hygiene, general care, and choice of complementary foods. The spread of HIV/AIDS has created another challenge for breastfeeding.

Ghana has in place legislation under the Food and Drugs Law to control the marketing of breast milk substitutes by baby food manufacturers. The legislative instrument Breastfeeding Promotions Regulation 2000 (L.I.1667) went into effect in May 2000. The purpose is to prevent the aggressive marketing of breast milk substitutes, hence protecting breastfeeding practices.

Table 10.4 shows the percentage of youngest children under three years of age living with the mother who consumed specific foods in the day or night preceding the interview, by breastfeeding status and age. It is important to note that the categories presented in Table 10.4 are not mutually exclusive. The child who consumed milk could also have consumed semi-solid foods. The data show that among breastfeeding infants in Ghana, very few receive infant formula. Forty-seven percent of breastfeeding children age 4-5 months are introduced to solid or semi-solid foods and 30 percent are introduced to foods made from grains.

Table 10.4 also shows that at the age of 6-9 months, more than 70 percent of breastfeeding infants received solid foods in the 24 hours before the survey. The majority (53 percent) consumed food made from grains, 29 percent received fruits and vegetables, and 21 percent received animal products (in addition to breast milk). Foods rich in vitamin A were consumed by only 24 percent of breastfeeding infants 6-9 months, and fats by only 8 percent. The findings indicate that, in terms of nutrition, the food mixtures given during this transition period are somewhat limited. By 10-11 months, almost all (91 percent) infants are receiving solids foods. This is a marked improvement over the 1998 GDHS figure of 73 percent for this age group (GSS and MI, 1999). By that same age, 10-11 months, a larger proportion are consuming grains (76 percent), fruits and vegetables (53 percent), and foods rich in vitamin A (46 percent). Although animal products (a major source of iron and vitamin A) are consumed by 46 percent of children in this age group, consumption of animal products is not as prevalent as the other foods. By 20-23 months, grains (84 percent), fruits and vegetables (62 percent), and foods rich in vitamin A (53 percent) are consumed by the majority of breastfeeding children; consumption of animal products increases slightly to 58 percent.

Few children under two years of age are not breastfed. For non-breastfeeding children about two years of age, the rates of consumption of food are about the same as for breastfeeding children; however, these children do not have the added nutritional benefit of breast milk, and very few receive other milk, but these children do consume more meat than breastfed children.

Percentage of youngest children under three years of age living with the mother who consumed specific foods in the day or night preceding the interview, by breastfeeding status and age, Ghana 2003

[1] Does not include plain water
[2] Includes fruits and vegetables rich in vitamin A
[3] Includes pumpkin, red or yellow yams or squash, carrots, red sweet potatoes, green leafy vegetables, mangoes, papayas, and other locally grown fruits and vegetables that are rich in vitamin A

10.2.2 Frequency of Foods Consumed by Children

Table 10.5 and Figure 10.2 present the mean number of times specific foods were consumed in the day or night preceding the interview by youngest children under three years of age living with the mother, according to breastfeeding status and age. Infants and young children eat small meals and, therefore, frequent meals are necessary to provide them with the required nutrients. It is recommended that children age 6-8 months eat a minimum of 2-3 meals and snacks per day in addition to breast milk. For children over 8 months of age, 3-5 meals should be consumed by breastfed children (WHO, 1998). The number of meals required is based on the energy density of the foods being fed. Consuming an appropriate variety of foods is essential for the child's nutrition.

Table 10.5 shows that on average foods made from grains are given to breastfeeding children only once a day from age 6-9 months, which is the best time for introducing complementary foods. Foods containing grain include flour made from maize, millet, or sorghum, which is used to make a fermented or

[1] Does not include plain water
[2] Includes fruits and vegetables rich in vitamin A
[3] Includes pumpkin, red or yellow yams or squash, carrots, red sweet potatoes, green leafy vegetables, mangoes, papayas, and other locally grown fruits and vegetables rich in vitamin A

unfermented porridge (*koko*). This food is consumed a little more than once a day through one year of age and twice a day at about two years of age for breastfed children.

At two years, non-breastfeeding children are receiving foods made from grain twice a day like breastfeeding children. Fruits and vegetables are consumed about twice a day by both breastfeeding and non-breastfeeding children at about two years. Foods enriched with oil/fat/butter—thereby increasing caloric intake—are consumed less than once a day. Animal products are consumed an average of once a day by both groups of children at two years of age.

Table 10.6 presents the mean number of days specific foods were received in the seven days preceding the interview by youngest children under three years of age, living with the mother, by breastfeeding status and age. Plain water is given almost on a daily basis. It also shows that foods most commonly given to children are those made from grains. They are given about four times a week. Animal products and green leafy vegetables are given three times a week.

10.3   MICRONUTRIENTS

Micronutrients are essential for the metabolic processes in the body and they play a major role in the nutrition and health of an individual. The 2003 GDHS collected various types of data that are useful in assessing the micronutrient status of young children and women.

10.3.1 Iodisation of Household Salt

In Ghana, a number of programmes aim at reducing micronutrient deficiencies. These include salt iodisation and vitamin A supplementation for children under five years of age through mass campaigns linked to national immunisation days. Vitamin A supplementation for children under five years of age and postpartum women (not later than 6 weeks after delivery) through routine health services has also begun but on a limited scale. Women are given vitamin A supplements during the postpartum period to assist both the mother and her breastfeeding children.

Disorders induced by dietary iodine deficiency constitute a major global nutrition concern. A lack of sufficient iodine can lead to goitre, hypothyroidism, impaired mental functions, retarded mental and physical development, and diminished school performance. Iodine deficiency in the foetus leads to increased rates of abortion, stillbirths, congenital anomalies, cretinism, psychomotor defects, and neonatal mortality. Iodine deficiency can be avoided by using salt that has been fortified with iodine (iodised salt).

Table 10.7 presents the percent distribution of households with salt tested for iodine content by level of iodine in salt (parts per million), percentage of households tested, and percentage of households with no salt, according to background characteristics. It shows that 90 percent of the households interviewed in the 2003 GDHS had their salt tested for iodine, while 9 percent had no salt available in the household. Fifty-nine percent of households are consuming salt that is not iodised, 13 percent of households are consuming inadequately iodised salt (<15 ppm), and only 28 percent are consuming adequately iodised salt (15+ ppm). Although Ghana has a salt iodisation law, there is need for more stringent enforcement and monitoring. The proportion of households with adequately iodised salt in rural areas (16 percent) is markedly lower than in the urban areas (44 percent). There are equally marked regional differences in adequacy of iodine levels in salt, ranging from 6 percent of households in the Northern and Upper East regions to 50 percent in the Greater Accra Region.

10.3.2 Micronutrient Intake among Children

Vitamin A is an essential micronutrient for the normal functioning of the visual system, growth and develoment, resistance to disease, and for reproduction. Vitamin A is believed to improve immunity and, hence, reduce mortality rates in children and women.

Table 10.8 shows the percentage of children under age three who consumed fruits and vegetables rich in vitamin A in the seven days preceding the survey, and the percentage of children age 6-59 months who received vitamin A supplements in the 6 months preceding the survey. It also indicates the percentage of children under five living in households that have adequately iodised salt.

Table 10.8 shows that 41 percent of children under three who live with their mothers consume fruits and vegetables rich in vitamin A. The fact that 78 percent of children 6-59 months are reported to have received a vitamin A supplement in the previous 6 months is encouraging. The data indicate that only 23 percent of children under the age of three live in households that use adequately iodised salt.

Consumption of vitamin A supplements is highest in the age group 24-35 months. There are no marked differences between the sexes on the consumption of vegetables and fruits rich in vitamin A, vitamin A supplements, or iodised salt. There is also little difference by birth order in the consumption of

Table 10.7 Iodisation of household salt

ppm=parts per million

vitamin A supplements or foods rich in vitamin A. However, children of birth order greater than three are less likely than children of birth order 1-3, to be living in households that use adequately iodised salt. As expected, non-breastfeeding children consume more micronutrient-rich foods than breastfeeding children. There are minimal differences between urban and rural children in the consumption of fruits and vegetables rich in vitamin A and vitamin A supplementation. Data also indicate that the consumption of foods rich in vitamin A is higher for children of women with a secondary or higher education compared with those with primary or no education. There are marked regional differences in micronutrient intake among children. For example, the level of vitamin A supplementation among children ranges from 67 percent in the Central Region to 86 percent in the Upper East Region.

Table 10.8 Micronutrient intake among children

Percentage of youngest children under age three living with the mother who consumed fruits and vegetables rich in vitamin A in the seven days preceding the survey, percentage of children age 6-59 months who received vitamin A supplements in the six months preceding the survey, and percentage of children under five living in households using adequately iodised salt, by background characteristics, Ghana 2003

 na = Not applicable
[1] Includes pumpkin, red or yellow yams or squash, carrots, red sweet potatoes, green leafy vegetables, mango, papaya, and other fruits and vegetables that are rich in vitamin A
[2] Salt containing 15 ppm of iodine or more. Excludes children in households in which salt was not tested.

10.3.3 Micronutrient Intake Among Mothers

It is recommended that mothers in Ghana be given two doses of vitamin A (24 hours apart) within 8 weeks of delivery. Mothers who deliver at health institutions are to receive a dose of vitamin A before they are discharged from the institution and given the second dose to take at home the following day. This is to boost the vitamin A level for their benefit and, through their breast milk, for the benefit of the child.

Table 10.9 shows the percentage of women with a birth in the five years preceding the survey who received a vitamin A dose in the first two months after delivery, the percentage who experienced night blindness during pregnancy, the percentage who took iron tablets for a specific number of days, and the percentage who live in households using adequately iodised salt, by background characteristics. The table shows that only 43 percent of mothers with a birth in the last five years reported receiving a vitamin A dose postpartum. Vitamin A supplementation is slightly higher among mothers of first births. Vitamin A supplementation among women is higher in urban areas (50 percent) than in rural areas (39 percent). The Upper East Region, where the programme was started before other regions, has the highest level of postpartum supplementation of vitamin A (73 percent), while the Western Region has the lowest (21 percent). This indicates the need for strengthening routine supplementation by health services immediately after a birth, because it is the best opportunity to capture most of the mothers.

Table 10.9 also shows that 8 percent of interviewed women reported night blindness during pregnancy. When the data are adjusted for blindness not attributed to vitamin A deficiency during pregnancy, only 2 percent of women reported night blindness during their last pregnancy. Women age 25-29 and those who have had six or more births are more likely to report a higher prevalence of night blindness associated with vitamin A deficiency during pregnancy. Night blindness is notably higher in the Upper West, Volta, and Northern regions of the country. Prevalence of night blindness is also higher among women with little or no education and women from the two lowest wealth quintiles.

Iron-deficiency anaemia is a major threat to maternal health; it contributes to low birth weight, lowered resistance to infection, poor cognitive development, and decreased work capacity. Furthermore, anaemia increases morbidity from infections because it adversely affects the body's immune response. According to the government policy, all pregnant mothers attending antenatal clinics are supposed to be given iron tablets during their pregnancy. International recommendations are that iron tablets be taken daily for at least three months during pregnancy. It should be noted that although four in five women reported having taken iron tablets during their pregnancy, only 40 percent took them for 90 or more days (Table 10.9).

According to the baseline study on prevalence and etiology of anaemia conducted in 1995 (GHS, 1995), 65 percent of pregnant women, 59 percent of lactating mothers, 71 percent of school-age children and 84 percent of preschool children were found to be anaemic. This situation poses a challenge to the Ghana government if morbidity and mortality due to anaemia and other micronutrient deficiencies is to be reduced.

Table 10.9 shows that only 24 percent of women live in households where adequately iodised salt is used. There are no marked differences in the level of micronutrient supplementation by mother's age at birth or number of children ever born.

Table 10.9 Micronutrient intake among mothers

Percentage of women with a birth in the five years preceding the survey who received a vitamin A dose in the first two months after delivery, percentage who suffered from night blindness during pregnancy, percentage who took iron tablets or syrup for specific number of days, and percentage who live in households using adequately iodised salt, by background characteristics, Ghana 2003

[2] Women who reported night blindness but did not report difficulty with vision during the day
[3] Salt containing 15 ppm of iodine or more. Excludes women in households in which salt was not tested.

10.3.4 Prevalence of Anaemia in Children

The most common causes of anaemia in Ghana are inadequate dietary intake of iron, malaria, and intestinal worm infestation (GHS, 2003a). Iron and folic acid supplementation and anti-malarial prophylaxis for pregnant women, promotion of the use of insecticide-treated bed nets by pregnant women and children under five, and six-month de-worming for children age two to five years are some of the measures being pursued by the Ghana Health Service to reduce anaemia prevalence among vulnerable groups.

Table 10.10 shows the percentage of children age 6-59 months classified as having anaemia, by background characteristics. Three-quarters of Ghanaian children 6-59 months old have some level of anaemia, including 23 percent of children who are mildly anaemic, 47 percent who are moderately anaemic, and 6 percent who are severely anaemic.

Prevalence of anaemia among children is higher in rural areas (80 percent) than in urban areas (68 percent). The Northern Region has the highest prevalence of anaemia (83 percent), while the Greater Accra Region has the lowest (61 percent). Prevalence of anaemia is also higher among children of mothers with little or no education, young mothers (15-19 years), and children in households in the two poorest wealth quintiles. This indicates the widespread nature of the problem and the need to intensify the various components of the anaemia control strategy.

10.3.5 Prevalence of Anaemia in Women

Table 10.11 presents information on prevalence of anaemia among women age 15-49. The prevalence of anaemia is less pronounced among women than among children. Forty-five percent of women age 15-49 are anaemic, with 35 percent mildly anaemic, 9 percent moderately anaemic, and less than 1 percent severely anaemic. Differences by urban-rural place of residence are not large. About half of women in seven regions in Ghana (including Greater Accra) suffer from some degree of anaemia. Women residing in Brong Ahafo Region are least likely to be anaemic. Lack of education, being pregnant, and living in poor households are also associated with higher prevalence of anaemia in women of childbearing age.

Table 10.10 Prevalence of anaemia in children

Percentage of children age 6-59 months classified as having anaemia, by background characteristics, Ghana 2003

Note: Table is based on women who stayed in the household the night before the interview. Women with <7.0 g/dl of hemoglobin have severe anaemia, women with 7.0-9.9 g/dl have moderate anaemia, and pregnant women with 10.0-10.9 g/dl and nonpregnant women with 10.0-11.9 g/dl have mild anaemia.
g/dl = grams per deciliter
[1] For women who are not interviewed, information is taken from the Household Questionnaire
[2] Excludes women who were not interviewed

10.3.6 Prevalence of Anaemia in Children by Anaemia Status of Mother

Table 10.12 shows the percentage of children age 6-59 months classified as anaemic, by the anaemia status of the mother. There is not a strong relationship between the anaemia status of mothers and the anaemia status of children except in the case of mothers with moderate anaemia, whose children are more likely to suffer from severe anaemia (9 percent) than children of mothers with no anaemia (5 percent) or those with mild anaemia (6 percent).

Table 10.12 Prevalence of anaemia in children by anaemia status of mother

Percentage of children age 6-59 months classified as having anaemia, by anaemia status of mother, Ghana 2003

| Anaemia status of mother | Any anaemia | Anaemia status of child | | | Number of children |
		Mild (10.0-10.9 g/dl)	Moderate (7.0-9.9 g/dl)	Severe (below 7.0 g/dl)	
No anaemia	73.3	23.0	45.0	5.3	1,391
Any anaemia	80.6	22.1	51.7	6.7	1,237
Mild anaemia	80.0	21.5	52.3	6.1	988
Moderate anaemia	83.1	24.2	50.0	8.8	239
Severe anaemia	*	*	*	*	10
Total	76.7	22.6	48.2	6.0	2,629

Note: Table is based on children who stayed in the household the night before the interview. Table includes only cases with anaemia measurements for both mothers and children. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.
g/dl = grams per deciliter

10.4 NUTRITIONAL STATUS OF CHILDREN UNDER AGE FIVE

The 2003 GDHS included information on the nutritional status of children under five years of age for three indices, namely, weight-for-age, height-for-age, and weight-for-height.

10.4.1 Measures of Nutritional Status in Childhood

In addition to questions on feeding practices associated with infant and young children, the 2003 GDHS included anthropometric measurements for all children under five years of age. Each interviewing team was equipped with a lightweight electronic SECA scale, designed and manufactured under the guidance of UNICEF, and a measuring board specifically produced by Shorr Productions for use in survey settings. Children younger than 24 months were measured lying down on the board (recumbent length), while standing height was measured for older children. The scale also allowed for the weighing of very young children, with an automatic mother-child adjustment, which eliminated the mother's weight while she stood with her baby on the weighing scale.

In previous GDHS surveys, anthropometric measurements were restricted to children born to women interviewed with the Women's Questionnaire. However, these data are not representative of all children, since they exclude children whose mothers were not in the household (either because they did not live there, or because they had died), children whose mothers were not eligible for the individual interview (i.e., under age 15 or age 50 and over), and children whose mothers did not complete an

individual interview. To overcome these biases, the 2003 GDHS included weight and height measurements of all children who were born in the five years preceding the survey and listed in the Household Questionnaire, irrespective of the interview status of their mother.

As recommended by the World Health Organisation (WHO), the anthropometric measurements of children in the survey are compared with an international reference population defined by the U.S. National Centre for Health Statistics (NCHS) and accepted by the U.S. Centres for Disease Control and Prevention (CDC). Each of the three nutritional status indicators described below are expressed in standard deviation units (Z-scores) from the median for the reference population. The use of this reference population is based on the finding that well nourished young children of all population groups (for which data exist) follow very similar growth patterns. The reference populations serve as a point of comparison, facilitating the examination of differences in the anthropometric status of subgroups in a population and changes in nutritional status over time. In any large population, there is variation in height and weight; this variation approximates a normal distribution.

Each of these indices—height-for-age, weight-for-height, and weight-for-age—gives different information about growth and body composition used to assess nutritional status. The height-for-age index is an indicator of linear growth retardation. Children whose height-for-age Z-score is below minus two standard deviations (-2 SD) from the median of the reference population are considered short for their age (stunted) and are chronically malnourished. Children who are below minus three standard deviations (-3 SD) from the median of the reference population are considered severely stunted. Stunting reflects failure to receive adequate nutrition over a long period of time and is also affected by recurrent and chronic illness. Height-for-age, therefore, represents the long-term effect of malnutrition in a population and does not vary according to recent dietary intake.

The weight-for-height index measures body mass in relation to body length and describes current nutritional status. Children whose Z-scores are below minus two standard deviations (-2 SD) from the median of the reference population are considered thin (wasted) for their height and are acutely malnourished. Wasting represents the failure to receive adequate nutrition in the period immediately preceding the survey and may be the result of inadequate food intake or a recent episode of illness causing loss of weight and the onset of malnutrition. Children whose weight-for-height is below minus three standard deviations (-3 SD) from the median of the reference population are considered severely wasted.

Weight-for-age is a composite index of height-for-age and weight-for-height. It takes into account both acute and chronic malnutrition. Children whose weight-for-age is below minus two standard deviations from the median of the reference population are classified as underweight.

Table 10.13 shows the percentage of children under five years classified as malnourished according to height-for-age, weight-for-height, and weight-for-age, by background characteristics. A total of 3,586 children under five were identified in the households. Eight percent of children had missing information on height or weight, 3 percent had implausibly high or low values for height or weight measures, and less than 1 percent had incomplete age information. The analysis on nutritional status is based on the remaining 89 percent or 3,183 children.

According to the 2003 GDHS, 30 percent of children under five are stunted and 11 percent severely stunted. Seven percent of children under five are wasted and 1 percent severely wasted. Weight-for-age results show that 22 percent of children under five are underweight, with 5 percent severely underweight.

Table 10.13 and Figure 10.3 indicate that stunting is evident among children as young as 6 months of age (6 percent). Stunting increases with the age of the child. This is evidenced by the marked increase in stunting levels from 14 percent at 6-9 months to 35 percent at age 12-23 months. There are no

marked differences between males (33 percent) and females (27 percent) in the levels of stunting among children under five years. Table 10.13 also shows that the longer the birth interval, the lower the stunting levels. Birth size is an important indicator of a child's nutritional status at birth and in the future. According to Table 10.13, a larger percentage of children who were reported to have been small or very small at birth were stunted (40 percent) compared with children who were average or larger in size at birth (27 percent).

Table 10.13 indicates that wasting is more common in the age group 6-23 months and decreases as the child ages. Weight-for-age is an index of chronic or acute malnutrition. It does not distinguish between a child who is underweight because of stunting or wasting. Underweight is very minimal for children less than 6 months of age but becomes more pronounced at age 6 months and above (during the normal complementary feeding period). This may be because most children are still primarily breastfeeding until 6 months of age.

Table 10.13 also shows that rural children are more likely to be stunted and underweight than urban children, while the proportion wasted is almost the same in both rural and urban areas (7 percent). Regional variation in nutritional status of children is substantial. The Central, Northern, Upper East and Upper West regions have stunting levels that are above the national average. Children living in the Upper East, Northern, and Upper West regions also have underweight levels above the national average, in addition to children from the Volta Region. Size at birth is also related to wasting in children; a larger percentage of children reported by mothers as very small at birth are wasted (12 percent), compared with those reported as average or larger (7 percent). Wasting is particularly high in the Volta, Upper East, and Upper West regions.

The percentage of malnourished children decreases with increasing level of mother's education. About a third of children whose mothers have no education are stunted or underweight. The pattern is less clear with levels of wasting. Mother's age has no marked influence on the nutritional status of the child. There are no strong differences by sex and birth order.

Table 10.13 indicates that children whose biological mothers were not in the household are more likely to be malnourished (34 percent stunted and 25 percent underweight) than children whose mothers were interviewed.

Poor nutritional status among children is obvious among those who live in poor households. For example, two-fifths of children who live in households in the lowest wealth quintile are stunted compared with one-eighth of children in the highest wealth quintile. A similar pattern is seen among children who are underweight. The relationship between wasting and wealth is not that strong.

Table 10.13 Nutritional status of children

Percentage of children under five years classified as malnourished according to three anthropometric indices of nutritional status: height-for-age, weight-for-height, and weight-for-age, by background characteristics, Ghana 2003

Note: Table is based on children who stayed in the household the night before the interview. Each of the indices is expressed in standard deviation units (SD) from the median of the NCHS/CDC/WHO International Reference Population. The percentage of children who are more than three or more than two standard deviations below the median of the International Reference Population (-3 SD and -2 SD) are shown according to background characteristics. Table is based on children with valid dates of birth (month and year) and valid measurement of both height and weight. Total includes 2 children with missing information on size at birth.
[1] Includes children who are below -3 standard deviations (SD) from the International Reference Population median
[2] Excludes children whose mothers were not interviewed
[3] First born twins (triplets, etc.) are counted as first births because they do not have a previous birth interval
[4] For women who are not interviewed, information is taken from the Household Questionnaire. Excludes children whose mothers are not listed in the household schedule.
[5] Includes children whose mothers are deceased
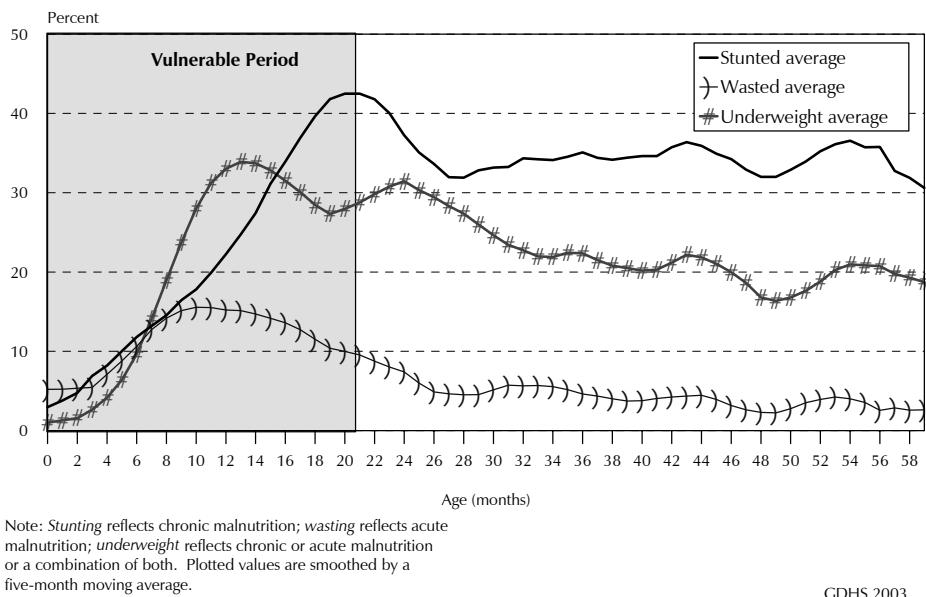

Figure 10.3
Stunting, Wasting, and Underweight by Age, Ghana

Note: *Stunting* reflects chronic malnutrition; *wasting* reflects acute malnutrition; *underweight* reflects chronic or acute malnutrition or a combination of both. Plotted values are smoothed by a five-month moving average.

GDHS 2003

10.4.2 Trends in Children's Nutritional Status

An analysis of trends in these data shows an increase in the level of stunting but slight decreases in the proportions of children who are wasted or underweight. Caution has to be exercised when comparing data from the various DHS surveys conducted in Ghana to assess the trend in the nutritional status. This is because information on children's nutritional status was gathered for different age groups from one survey to another. In addition, previous DHS surveys collected anthropometric measurements only for children of interviewed women, whereas the 2003 survey collected nutritional status information from all children under age five living in the household at the time of the interview. While it is possible to adjust for some of these inconsistencies, it is not possible to correct them all. Comparisons are therefore restricted to the last five years.

The proportion of children under five who are stunted has increased from 26 percent in 1998 to 30 percent in 2003. The proportion underweight decreased from 10 percent in 1998 to 7 percent in 2003. The proportion of children who are wasted also decreased from 25 percent in 1998 to 22 percent in 2003 (GSS and MI, 1999). These trends in nutritional status imply that the problem of malnutrition in Ghana may be due to chronic food shortages. This is evidenced by the fact that the three northern regions, which have annual periods of drought, have consistently recorded the highest levels of stunting.

10.5   NUTRITIONAL STATUS OF WOMEN

The 2003 GDHS collected information on the height and weight of women. The data were used to derive two measures of nutritional status, height and body mass index (BMI). A woman's height may be used to predict the risk of difficulty in delivery (given the relationship between height and the size of the pelvis). The risk of giving birth to a low-birth-weight baby is influenced by the mother's nutritional status. The cut-off point for height at which mothers can be considered at risk varies between populations but normally falls between 140 centimetres and 150 centimetres; a cutoff point of 145 centimetres is used here. The index used to measure thinness or obesity is known as the body mass index (BMI), or the

Quetelet index. BMI is defined as weight in kilogrammes divided by height squared in metres (kg/m^2). A cut-off point of 18.5 is used to define thinness or acute undernutrition. A BMI of 25 or above usually indicates overweight or obesity.

The 2003 GDHS collected anthropometric information for all women age 15-49, in contrast to earlier surveys, which restricted anthropometric data collection to women who had a live birth in the five years (or three years) preceding the survey. As such, this is a more representative sample because it includes both younger women who may not yet have given birth and older women who would have stopped childbearing. Women for whom there was no information on height and/or weight and for whom a BMI could not be estimated are excluded from this analysis.

Table 10.14 shows the nutritional status of women in the reproductive ages 15-49. The mean height of women is 159 centimetres, which is above the critical height of 145 centimetres. Nine percent of women are found to be chronically malnourished (BMI less than 18.5), while 25 percent are overweight. Variations between urban and rural women are marked. More women have a BMI less than 18.5 in rural areas (12 percent) than in urban areas (6 percent). The percentage of overweight or obese women is, however, higher in urban areas (35 percent) than in rural areas (16 percent). The Greater Accra Region has the highest percentage of these women (46 percent) and the Upper West Region has the lowest percentage (7 percent). The percentage of overweight or obese women increases with increasing educational level as well as increasing wealth quintile.

Interpretation of trends in women's nutritional status is complicated by the fact that in the 1993 and the 1998 GDHS only mothers of children under five were measured. In 2003, the data refer to all women age 15-49. A comparison, restricting the data for 2003 to mothers of children under five years, shows that there has been little change in the percentage of mothers whose height is below 145 centimetres and in the mean BMI over the past ten years, from 1993 to 2003. However, there has been a small decline in the percentage of mothers who fall below a BMI of 18.5, from 11 percent in 1993 and 1998 to 9 percent in 2003.

Table 10.14 Nutritional status of women by background characteristics

Among women age 15-49, mean height, percentage under 145 cm, mean body mass index (BMI), and percentage with specific BMI levels, by background characteristics, Ghana 2003

[1] Excludes pregnant women and women with a birth in the preceding 2 months

MALARIA

11

Malaria is endemic throughout Ghana and continues to be a major public health concern. It is one of the leading causes of morbidity and mortality, especially among pregnant women and children under the age of five. The Ministry of Health (MoH) estimates that over the past ten years, there have been 2-3 million cases of malaria each year, representing 40 percent of outpatient cases, while severe malaria accounts for 33-36 percent of in-patients. Malaria also accounts for 25 percent of the deaths in children under the age of five (GHS, 2001).

Since 1999, Ghana has been involved in the international efforts to control malaria under the Roll Back Malaria (RBM) initiative. The objectives of this initiative are to ensure that by the year 2005 at least 60 percent of those at risk of malaria, particularly pregnant women and children under five, have access to the most suitable and affordable combination of personal and community protective measures such as insecticide treated mosquito nets (ITNs) and prompt, effective treatment for malaria. Another objective is to ensure that at least 60 percent of all pregnant women who are at risk of malaria, especially those in their first pregnancies, have access to chemoprophylaxis or intermittent preventive treatment (IPT).

11.1   MOSQUITO NETS

11.1.1 Ownership of Mosquito Nets

The ownership and use of mosquito nets, both treated and untreated, is the primary health intervention for reducing malaria transmission and morbidity in a community prone to the vector—the Anopheles mosquito. In Ghana, there are various types of ITNs available on the market. They include the long-lasting ones that require re-treatment after about five years and others that need to be re-treated every six months or after three washes.

In an effort to make mosquito nets more affordable, the Government of Ghana has since 2002 waived taxes on the importation of nets into the country. Developmental partners have also contributed by supplying some ITNs for distribution at subsidised costs to pregnant women and children under five in deprived areas of the country. These nets are distributed through routine public health services.

Table 11.1 shows the percentage of households with at least one and more than one mosquito net (treated or untreated), and the percentage of households that have at least one and more than one ITN by their background characteristics. The data show that 18 percent of households in Ghana own a mosquito net whether treated or untreated. About 6 percent of households own more than one net. Only 3 percent of households own at least one currently treated net (ITN). Rural households are more likely to own any kind of net (24 percent) compared with urban households (10 percent). Mosquito net ownership is highest in the Volta Region (46 percent) and lowest in the Central Region (9 percent).

Table 11.1 Ownership of mosquito nets

Percentage of households (HH) with at least one and more than one mosquito net (treated or untreated), percentage of households that have at least one and more than one ever-treated net, and the percentage of households that have at least one and more than one insecticide-treated net (ITN), by background characteristics, Ghana 2003

| Background characteristic | Percentage of house-holds that have: | | Average number of nets per HH | Percentage of house-holds that have: | | Average number of ever-treated nets per HH | Percentage of house-holds that have: | | Average number of ITNs[1] per HH | Number of households |

[1] An insecticide treated net (ITN) is a long lasting net that does not require frequent treatment, a pretreated net obtained within the last six months, or a net that has been soaked with insecticide within the past six months

With regard to ITNs. Households in the Eastern Region report the lowest ownership of ITNs (1 percent), while those in the Upper East Region (25 percent) have the highest level of ITN ownership, followed by the Northern Region (8 percent). The high level of ownership of ITNs in the Northern and Upper East regions may be attributable to the fact that UNICEF has since 2002 been distributing ITNs at highly subsidised costs to pregnant women and children under five in the Northern and Upper East regions as part of its Child Survival and Reproductive Health programmes. Interestingly, although the Northern Region has benefited from the same programme, ownership of ITNs in the region is not that high, though it is still higher than ownership of ITNs recorded in eight other regions.

11.1.2 Use of Mosquito Nets by Children

In the 2003 GDHS, respondents to the Household Questionnaire were asked about the use of mosquito nets by all members of the household the night before the interview.

Table 11.2 presents information on the percentage of de facto children under age five years who slept under a mosquito net the night before the survey and the percentage that slept under an ITN by background characteristics. The data show that 15 percent of children under five years slept under a

mosquito net (treated or untreated) the night before the survey. Five percent of children slept under an ever-treated net while 4 percent are reported as having slept under an ITN the night prior to the survey. Children one year of age and younger are most likely to have slept under any net, an ever-treated net, or an ITN. Children in rural areas are twice as likely to sleep under a mosquito net (18 percent) than their urban counterparts (9 percent). The proportion of children who sleep under any type of mosquito net was highest in the Volta Region (44 percent) and lowest in the Central Region (5 percent) and lowest among children in the highest wealth quintile, presumably because more of these children live in houses that have window netting.

Table 11.2 Use of mosquito nets by children

Note: Based on de facto children in the household.
[1] An insecticide treated net (ITN) is a long lasting net that does not require any treatment, a pretreated net obtained within the last six months, or a net that has been soaked with insecticide within the past six months

ITN use is not affected by residence and shows a U-shaped pattern according to the wealth index. i.e., greatest use of ITNs in households in the lowest and highest wealth quintiles. The percentage of children who sleep under an ever-treated net or ITN is highest in the Upper East Region and lowest in the Eastern Region.

11.1.3 Use of Mosquito Nets by Pregnant Women

Malaria is especially dangerous during pregnancy and this has prompted many advocacy campaigns to educate not only pregnant women, but also the general public on the importance of preventing malaria during pregnancy. Table 11.3 shows the percentage of all de facto women and de facto pregnant women who slept under a mosquito net whether treated or untreated, and the proportion who slept under an ITN the night prior to the survey, by background characteristics. The data show no difference in the use of nets between pregnant and nonpregnant women. Ten percent of pregnant women slept under a net, 4 percent slept under an ever-treated net, and 3 percent slept under an ITN the night before the interview.

Table 11.3 Use of mosquito nets by pregnant women

Percentage of all women and pregnant women age 15-49 who slept under a mosquito net (treated or untreated), who slept under an ever-treated net, and who slept under an insecticide-treated net (ITN) the previous night, by background characteristics, Ghana 2003

Background characteristic	Percentage of women who:				Percentage of pregnant women who:			
	Slept under net the previous night	Slept under ever-treated net the previous night	Slept under ITN[1] the previous night	Number of women	Slept under net the previous night	Slept under ever-treated net the previous night	Slept under ITN[1] the previous night	Number of pregnant women

[1] An insecticide treated net (ITN) is a long lasting net that does not require any treatment, a pretreated net obtained within the last six months, or a net that has been soaked with insecticide within the past six months

Women in rural areas are about three times more likely to sleep under a mosquito net than urban women, while rural pregnant women are about twice as likely to sleep under a net as urban pregnant women. As was seen in the data for children, use of mosquito nets among all women is highest in the Volta Region (35 percent) and lowest in the Central Region (4 percent). In general, the use of mosquito nets (treated and untreated) decreases among women as the level of wealth increases. However, this is not the case among pregnant women. Use of mosquito nets by pregnant women shows a U-shaped pattern by wealth index, although women in the highest wealth quintile are slightly less likely than women in the lowest wealth quintile to sleep under any net, treated or untreated. This could be due in part to the fact that many women from wealthy households and urban dwellers live in houses with mosquito screening on windows and doors, hence the redundancy of mosquito net use.

11.2 EXPOSURE TO MEDIA MESSAGES ON MALARIA

The 2003 GDHS included a series of questions at the household level on media exposure to information on malaria. The respondents to the Household Questionnaire were asked if they had seen or heard any messages about malaria on various media sources or any messages telling them to give a child with fever chloroquine tablets for three days, and if they had specifically listened to the radio program *He Ha Ho*. This information is shown in Table 11.4.

Table 11.4. Exposure to messages on malaria

Percentage of household respondents who heard or saw a message on malaria through various media sources, percentage who heard or saw a message telling them to give a child with fever chloroquine tablets for three days, and percentage who ever listened to the radio program *He Ha Ho*, according to background characteristics, Ghana 2003

Total	50.2	84.4	19.9	41.5	13.5	41.2	10.6	81.9	41.7	6,251

The majority of household respondents said they had heard about malaria on the radio (84 percent), half have seen a message about malaria on the television, while more than two-fifths of respondents have seen a poster on malaria or heard about malaria from a health worker. One-fifth of respondents have read about malaria in a newspaper or magazine and 14 percent have seen leaflets or brochures on malaria. One in ten respondents have had no exposure to malaria messages. Eighty-two percent of respondents have heard or seen a message telling them to give a child with fever chloroquine tablets for three days, and 42 percent of them have heard the radio programme *He Ha Ho*. Exposure to media messages on malaria is much higher in urban than rural areas, highest in the Brong Ahafo Region, and among those in the highest wealth quintile.

11.3 MALARIA DIAGNOSIS, CASE MANAGEMENT, AND TREATMENT

11.3.1 Malaria Prophylaxis during Pregnancy

One of the strategies the MoH and the Ghana National Malaria Control Programme has adopted for malaria control is the Intermittent Preventive Treatment (IPT) of pregnant women with sulphadoxine-pyrimethamine (SP), also known as Fansidar. According to this policy, from the second trimester of pregnancy (after quickening), pregnant women are expected to receive three doses of SP, at monthly intervals (GHS, 2003b). This replaces the former policy of giving a full dose of chloroquine for treatment at first antenatal visit followed by two tablets weekly till 6 weeks postpartum (GHS, 2003c). This policy decision was finalised at the end of 2003, hence during the period of data collection for the 2003 GDHS the old policy was still in force. The data on anti-malarial drugs from the 2003 GDHS depend on accurate reporting of types of drugs taken. It is likely that some women are not sure of the type of drug they took during pregnancy or gave to their children.

Table 11.5 shows the percentage of women with a birth in the five years preceding the survey who took any anti-malarial drug two or more times for prevention of malaria during their pregnancy, those who took chloroquine, and those who took Fansidar (SP) by background characteristics. The data show that 58 percent of mothers reported that they took some anti-malarial drug for the prevention of malaria when pregnant. It also shows that chloroquine is more frequently (12 percent) used than SP (1 percent), presumably because the old programme was still in force during the fielding of the survey. The 1 percent of women who used SP received the drug during an antenatal visit. The data imply that the majority of women either took other drugs apart from chloroquine or SP, or did not know whether the drug contained chloroquine or Fansidar. Chloroquine is sold under many different brand names, and women may not realise that the active ingredient in their drug is still chloroquine.

Urban women (67 percent) are more likely to take anti-malarial drugs during pregnancy than rural women (53 percent). The Brong Ahafo Region (72 percent) has the highest percentage of women taking any anti-malarial drug, while Upper West (21 percent) has the lowest. The use of anti-malarial drugs during pregnancy increases with increasing levels of wealth and education.

The use of IPT by pregnant women for the last birth in the year preceding the survey can serve as a baseline for the newly instituted IPT programme. As expected, only 1 percent of women with a birth in the 12 months preceding the survey received Fansidar during their ANC visit. Most of them were from the Upper East Region (data not shown).

Table 11.6 shows, among mothers who took anti-malarial drugs for prevention during the last pregnancy leading to a live birth in the five years preceding the survey, the percentage who took sulfadoxine-pyrimethamine (SP/Fansidar) by background characteristics. Two percent of mothers took Fansidar during their last pregnancy. Among mothers who took Fansidar, most took it more than three times and four in five received it during an antenatal visit (data not shown).

Table 11.5 Use of Intermittent Preventive Treatment (IPT) by pregnant women

Among women who gave birth in the five years preceding the survey, percentage who took anti-malarial drugs for prevention of malaria during the most recent pregnancy leading to a live birth, and percentage who received intermittent preventive treatment (IPT) with chloroquine or sulphadoxine pyrimethamine (SP/Fansidar), by background characteristics, Ghana 2003

11.3.2 Prevalence and Management of Childhood Malaria

Since the major manifestation of malaria is fever, in the 2003 GDHS mothers were asked whether their children under age five had a fever in the two weeks preceding the survey. Although fever can occur all year round, malaria is more prevalent during the rainy season, and such temporal factors must be taken into account when interpreting the occurrence of fever as an indicator of malaria prevalence. If a fever was reported, the mother was asked whether treatment was sought at a health facility and whether the child was given any medication and, if so, how soon the medication was taken after the episode of illness started.

Table 11.7 shows the percentage of children under age five with fever in the two weeks preceding the survey, and among children with fever, the percentage who took anti-malarial drugs and the percentage who took anti-malarial drugs the same or next day, by background characteristics. Twenty-one percent of children under five years had a fever in the two weeks preceding the survey. Of these, 63

percent of children took an anti-malarial drug. Forty-four percent of children took the anti-malarial drug on the same or the next day after the onset of the illness.

Table 11.7 Prevalence and prompt treatment of fever

Total	21.3	3,340	62.8	44.2	710

Note: Figures in parentheses are based on 25-49 unweighted cases..

The highest prevalence of fever is reported among children age 12-23 months (28 percent), followed by those age 24-35 months (25 percent). Fever is less common among children age less than 12

months and those age 48-59 months (18 percent). The proportion of children with fever differs little by gender of the child and urban-rural residence. The Volta and Upper West regions have the highest percentage of children with fever (about 30 percent), while the Northern Region has the lowest (16 percent). There is no clear association between the prevalence of fever and wealth. The prevalence of fever is highest among children of highly educated mothers. It is plausible that highly educated mothers are more likely to recognize and report the prevalence of fever than poorly educated mothers.

Children age 36-47 months are most likely to be given anti-malarial drugs for the treatment of fever and are also most likely to receive the drugs the same or the next day. Differences by gender are minimal. Children living in the urban areas are slightly more advantaged than children in the rural areas to be given anti-malarial drugs and within a day or two. Children living in the Upper East Region are most likely to have been given an anti-malarial drug (71 percent), but together with the Upper West Region, the least likely to have taken the drugs the same or the next day. On the whole, children in the Brong Ahafo Region are most likely to receive anti-malarial drugs within a day or two. There is no clear association between the intake of anti-malarial drugs and wealth; nevertheless, children living in households that are relatively wealthy (fourth wealth quintile) are most likely to be given anti-malarial drugs and within the first day or two of fever. Even though education does not exert a strong positive impact in determining if mothers give children anti-malarial drugs, children of highly educated mothers are much more likely than children of other mothers to be given these drugs the same day or the next.

Table 11.8 presents information on the type and timing of anti-malarial drugs given to children under age five with fever in the two weeks preceding the survey, the percentage who took specific anti-malarial drugs and the percentage who took each type of drug the same or next day after developing fever, by background characteristics. Chloroquine is by far the most common anti-malarial drug given for fever (59 percent), followed by Amodiaquine and Quinine (2 percent each) and Fansidar (less than 1 percent). It is noteworthy that although the use of quinine to treat malaria is relatively low in the country as a whole, one in ten children residing in the Upper West Region has been treated with quinine.

Forty-four percent of children took chloroquine the same or the next day following the onset of fever. Children age 36-47 months are more likely than other children to be treated with chloroquine for malaria. About three in five children in both the urban and rural areas took chloroquine, but urban children are more likely than rural children to have received the drug within a day or two following the onset of fever. About two-thirds of children in the Western, Greater Accra, Volta, Eastern, Brong Ahafo, and Upper East regions received chloroquine and about one in two children residing in the Western, Volta, Eastern, and Brong Ahafo regions took chloroquine the same day or the next. Children in the middle or higher wealth quintiles are more likely than other children to have received chloroquine within a day or two of developing a fever. Children of highly educated mothers also have a slight advantage over other children in receiving some malaria treatment and receiving it promptly.

Table 11.8 Type and timing of anti-malarial drugs

Among children under age five with fever in the two weeks preceding the survey, percentage who took specific anti-malarial drugs and the percent-age who took each type of drug the same/next day after developing fever, by background characteristics, Ghana 2003

HIV/AIDS-RELATED KNOWLEDGE, ATTITUDES, AND BEHAVIOR

12

Acquired immune deficiency syndrome (AIDS) was first recognised internationally in 1981. Today it is a serious problem in much of the world, with countries in sub-Saharan Africa, and especially those located in the east, central, and southern parts of the continent, most affected. The growing AIDS epidemic threatens to halt social and economic gains in many countries, especially in Africa. In Ghana, as in the rest of Africa, sexual (especially heterosexual) contact and mother-to-child transmission (MTCT) are the two most common ways HIV/AIDS infections are spread.

HIV was first identified in Ghana in March 1986. Since then the epidemic has spread slowly but steadily. Ghana initially responded to HIV/AIDS as a health rather than a developmental issue and consequently directed the Ministry of Health (MOH) to address the problem. In 1987, the National AIDS Control Programme (NACP) was established under the MOH to implement and coordinate the country's HIV/AIDS programme. In addition, a National HIV/AIDS and STI Policy was developed to guide the national response. The MOH through the NACP has spearheaded various strategies to contain and limit the spread of HIV infection. These strategies include maintaining a safe blood supply, ensuring safe use of needles, and disseminating information through public campaigns to change social attitudes and behaviour. In 2000, when it became apparent that HIV prevalence rates were steadily increasing, the government established the Ghana AIDS Commission (GAC) for effective resource mobilization, management, and co-ordination of HIV/AIDS activities and targeted prevention measures expected to successfully raise awareness and promote behavioural change among the population. The national HIV/AIDS Strategic Framework developed in 2001 provides goals and objectives for a national response to the disease.

Questions in the 2003 GDHS provide a unique opportunity to determine the level of awareness and practice regarding the transmission of the AIDS virus. Both female and male respondents were asked if they have ever heard of AIDS; what a person could do to avoid getting AIDS; if they know a person with AIDS or who died of AIDS; if they are aware of MTCT; and if they ever talked to their spouse about ways of preventing AIDS. Other questions concerned the extent of stigma or discrimination towards people living with HIV/AIDS (PLWHA), attitudes towards teaching children about condom use, testing for HIV/AIDS, knowledge of other sexually transmitted infections (STIs) and infection with STIs.

12.1   HIV/AIDS–RELATED KNOWLEDGE AND ATTITUDES

Table 12.1 shows that 98 percent of women and 99 percent of men have heard of AIDS, indicating that awareness of AIDS in Ghana is universal. There is little variation in knowledge among both men and women by background characteristics; however, awareness is somewhat lower among women in the Northern Region (88 percent).

Although most respondents have heard about AIDS, personal knowledge about PLWHAs or persons who have died of AIDS is low for both men and women. Thirty-seven percent of women and 38 percent of men age 15-49 know someone personally who has the virus that causes AIDS or who has died of AIDS. Women in the Ashanti (49 percent) and Brong Ahafo (48 percent) regions are most likely to know someone personally who has the virus or who has died of AIDS. Fifty-eight percent of men in the Upper East Region know someone personally who has the virus or has died of AIDS. Personal knowledge of someone with AIDS increases with the educational level of respondents from 31 percent among women with no education to 41 percent among those with at least secondary education. Comparable percentages for men are 34 and 44 percent, respectively.

Table 12.1 Knowledge of AIDS

Percentage of women and men age 15-49 who have heard of AIDS and who know someone personally who has the virus that causes AIDS or has died of AIDS, by background characteristics, Ghana 2003

12.2 KNOWLEDGE OF PREVENTION METHODS

Controlling the spread of HIV is one of the major objectives in the fight against HIV infection. The challenge is to substantially reduce new HIV infections among the sexually active population and other vulnerable groups. This is done through the promotion of safer sexual behaviour including

abstinence, condom use, and promoting sex with a single partner who is not infected and who has no other partners.

Table 12.2 shows the percentage of women and men age 15-49 who, in response to a prompted

Table 12.2 Knowledge of HIV prevention methods

Percentage of women and men age 15-49 who, in response to a prompted question, say that people can reduce the risk of getting the AIDS virus by using condoms and by having sex with just one partner who is not infected and who has no other partners, by background characteristics, Ghana 2003

question, say that people can reduce the risk of getting the AIDS virus by using condoms, by having sex with just one uninfected partner who has no other partners, and by abstaining from sex, by background characteristics.

Knowledge of HIV prevention methods is quite high. Seventy-three percent of women and 82 percent of men know that condom use is a major prevention method. Eighty-six percent and 90 percent of women and men, respectively, know that limiting sex to only one uninfected partner is vital to the prevention of HIV. Sixty-nine percent of women and 78 percent of men know that these two preventive measures in combination can reduce the risk of HIV infection. In addition, 79 percent of women and 83 percent of men know that abstinence can prevent HIV infection. Female respondents who are either married or living together and male respondents who have never had sex are slightly less knowledgeable about the principal ways to prevent HIV transmission than their counterparts.

Knowledge of HIV prevention is higher among urban than rural dwellers. Regional variations range from a low of 43 percent in the Northern Region to a high of 79 percent in the Upper East among women, and from a low of 56 percent in the Northern Region to a high of 89 percent in the Eastern Region among men. Knowledge of HIV prevention rises with education levels and wealth. There is no clear pattern between knowledge of HIV prevention and age.

12.3   BELIEFS ABOUT AIDS

Misconception about AIDS and HIV transmission is one of the factors that influences discrimination and stigmatisation. The 2003 GDHS inquired about common misconceptions in Ghana. Respondents were asked whether they think it is possible for a healthy-looking person to have the AIDS virus; whether AIDS can be transmitted by mosquito bites; whether AIDS can be transmitted by supernatural means; and whether a person can be infected through sharing food with a person who has AIDS. The results are presented in Tables 12.3.1 for women and 12.3.2 for men, by background characteristics.

About four in five women and men correctly know that a healthy looking person can have the AIDS virus. Fifty-five percent of women and 60 percent of men know that AIDS cannot be transmitted through mosquito bites. Less than half of women and three-fifths of men know that AIDS cannot be transmitted by supernatural means. More than 70 percent of women and men know that a person cannot become infected with HIV/AIDS by sharing food with someone who has AIDS. Only 28 percent of women and 39 percent of men believe that a healthy looking person can have the AIDS virus and also reject the two most common misconceptions about AIDS in Ghana (i.e., AIDS can be transmitted by mosquito bites and by supernatural means). It is evident from the survey data that misconceptions about AIDS transmission are high in Ghana.

Beliefs on HIV/AIDS transmission vary by residence. Urban residents are much less likely to have misconceptions about HIV/AIDS transmission than rural residents. For example, 50 percent of urban men age 15-49 compared with 29 percent of men residing in rural areas, believe that a healthy looking person can have the AIDS virus, and that a person cannot become infected with AIDS through mosquito bites and supernatural means. Regional variations are marked, with correct beliefs ranging from a low of 20 percent in the Central and Northern regions to a high of 52 percent in the Upper East Region among women, and from a low of 28 percent in the Northern Region to a high of 53 percent in Greater Accra among men. Education and wealth are positively correlated with correct beliefs.

Table 12.3.1 Beliefs about AIDS: women

Percentage of women age 15-49 who know that a healthy-looking person can have the AIDS virus and who in response to a prompted question, correctly reject local misconceptions about AIDS transmission or prevention, by background characteristics, Ghana 2003

Note: The two most common local misconceptions involve transmission by mosquito bites and by supernatural means.

12.4   STIGMA AND DISCRIMINATION ASSOCIATED WITH HIV/AIDS

The survey indicates that knowledge and beliefs about HIV and AIDS influence how PLWHAs and those affected by HIV/AIDS are treated. The extent of stigma and discrimination associated with HIV/AIDS can be ascertained from four questions included in the GDHS: whether respondents are willing to care for a family member with HIV at home; whether respondents would buy fresh vegetables from a vendor who has the AIDS virus; whether respondents believe that a female teacher who had the AIDS virus should be allowed to continue teaching; and whether respondents would want to keep the HIV positive status of a family member a secret. The results are shown in Tables 12.4.1 and 12.4.2.

It is encouraging to see that more than two-thirds of women and men age 15-49 are willing to care for a family member with HIV in their own household, and that three-fifths of women and two-thirds of men do not believe that the HIV-positive status of a family member should be kept a secret. Two-fifths of women and half of men also believe that an HIV-positive female teacher should be allowed to continue teaching. However, only one in four women and one in three men say that they would buy fresh vegetables from a vendor with AIDS. The four measures can be combined to provide a single measure of the percentage of women and men who exhibit accepting attitudes towards persons who have AIDS. It is disappointing to note that fewer than 10 percent of women and 14 percent of men express accepting attitudes on all four measures. Urban dwellers, those residing in Greater Accra, those with secondary education or higher, and those in the highest wealth quintile are much more likely to express accepting attitudes towards people with AIDS than others.

Table 12.4.1 Accepting attitudes towards those living with HIV: women

Percentage of women age 15-49 who have heard about AIDS expressing accepting attitudes towards people with HIV, by background characteristics, Ghana 2003

Background characteristic	Percentage of respondents who:				Percentage expressing accepting attitudes on all four measures	Number of women who have heard of HIV/AIDS
	Are willing to care for a family member with HIV at home	Would buy fresh vegetables from a vendor with AIDS	Believe HIV-positive female teacher should be allowed to continue teaching	Believe HIV-positive status of a family member does not need to remain a secret

12.5 KNOWLEDGE OF PREVENTION OF MOTHER-TO-CHILD TRANSMISSION

More than 80 percent of the transmission of HIV is through sexual intercourse. According to the Ghana HIV/AIDS strategic framework, mother to child transmission (MTCT) is estimated to account for about 15 percent of all HIV transmissions in Ghana. One of the key intervention areas of the HIV/AIDS strategic framework for Ghana is the prevention of new infections. The challenge is to make MTCT prevention services available and utilized. It is therefore important to ascertain the knowledge of respondents on how transmission of HIV from mother to child during pregnancy, delivery, and during breastfeeding can be prevented, and to ascertain whether women and men know that the risk of mother to child transmission of HIV can be reduced by the mother taking special drugs during pregnancy.

Tables 12.5.1 and 12.5.2 show that general knowledge about HIV transmission during pregnancy, delivery, and breastfeeding is relatively high and ranges between 69 and 75 percent among women and 74 to 82 percent among men. However, few women and men (16 percent each) know that the risk of MTCT can be reduced if a mother takes special drugs during her pregnancy. As seen before, urbanization, education, and wealth, have a positive impact on respondent's knowledge of MTCT. Women in the Upper West Region and men in the Northern Region are least likely to know both that HIV can be transmitted through breastfeeding and that the risk of MTCT can be reduced by mothers taking special drugs during pregnancy (a UNAIDS measure).

Table 12.5.1 Knowledge of prevention of mother to child transmission of HIV: women

Percentage of women age 15-49 who know that HIV can be transmitted from mother to child during delivery, during pregnancy and by breastfeeding and that the risk of mother-to-child transmission (MTCT) of HIV can be reduced by the mother taking special drugs during pregnancy, by background characteristics, Ghana 2003

12.6   HIV TESTING

Voluntary counselling and testing (VCT) is vital in the fight against HIV/AIDS. The 2003 GDHS asked all respondents who had heard of AIDS whether they had ever been tested for the virus, when they were last tested, whether the test was voluntary or mandatory, whether they received the test results, where they went for the test, and if they have not been tested, whether they would like to be tested, and whether they know where to go for the test.

Table 12.6, which presents results among all respondents, shows that only about one in ten women and men age 15-49 reported that they had ever been tested for AIDS. The majority of women and men who were tested know their HIV status. Two percent of women and 3 percent of men in Ghana have been tested and received their test results within the last 12 months.

Table 12.6 Women and men who had an HIV test and received test results

Percent distribution of women and men age 15-49 by status of HIV testing, and percentage of women and men who were tested for HIV and received test results in the past 12 months, according to background characteristics, Ghana 2003

12.7 COUNSELLING AND TESTING PREGNANT WOMEN

The need for voluntary counselling before testing for HIV cannot be over-emphasized. An opportunity for counselling pregnant women on HIV/AIDS arises during antenatal visits. The 2003 GDHS asked women who gave birth in the two years preceding the survey whether they were given any information or counselled about HIV/AIDS.

The results in Table 12.7 show that 1,421 women age 15-49 had a birth in the two years preceding the survey. Forty-three percent of these women were counselled during their antenatal visits. Eight percent of these women were voluntarily tested for AIDS, half of whom received their results while half

Table 12.7 Pregnant women counselled and tested for HIV
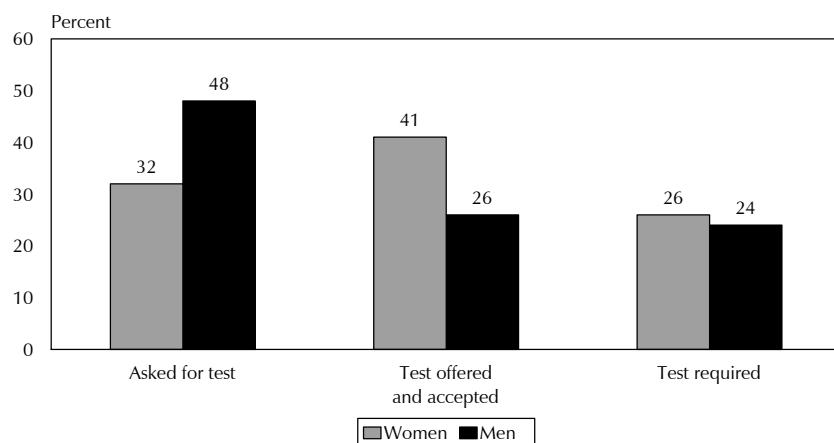

Among women who gave birth in the two years preceding the survey, percentage who were counselled and offered HIV testing during antenatal care for their most recent birth, percentage who accepted an offer of testing, and percentage who received their test results, by background characteristics, Ghana 2003

did not. Three percent of women who had a birth in the past two years were counselled, tested, and given the results of their test. VCT is more common among urban than rural women, and is highest in the Brong Ahafo Region. The percentage of women receiving VCT is positively related to both education and wealth status.

Among those who were tested for HIV, 32 percent of women and 48 percent of men asked for the test, while 41 percent of women and 26 percent of men were offered the test and accepted (Figure 12.1). About one-fourth of those tested (26 percent of women and 24 percent of men) indicated that the HIV test was required.

Figure 12.1 Reason for Getting HIV Test among Women and Men Age 15-49 Who Have Ever Been Tested

GDHS 2003

12.8 ATTITUDES TOWARDS NEGOTIATING SAFER SEX

Respondents in the GDHS were asked about their attitude towards negotiating safer sex. Women and men were asked if a wife is justified in refusing to have sexual intercourse with her husband if she knows that he has an STI. The majority of women (86 percent) and men (91 percent) agreed that a wife is justified in refusing to have sexual intercourse with her husband if he has an STI (Table 12.8). Men were also asked if a wife is justified in asking a man to use a condom if he has an STI. Again, most men (92 percent) agreed with this statement. A similar question was not posed to women. There is little variation by background characteristics.

Table 12.8 Attitudes towards negotiating safer sex with husband

Percentage of women and men age 15-49 who believe that, if a husband has an STI, his wife can refuse to have sex with him and percentage of men who believe that, if a husband has an STI, his wife can either refuse to have sex with him or propose condom use, by background characteristics, Ghana 2003

12.9   HIGHER-RISK SEX AND CONDOM USE

Sexual intercourse with a non-marital or non-cohabiting partner is associated with an increase in the risk of contracting STIs. Higher-risk sexual behaviour can therefore be defined as having sexual intercourse with any persons other than a spouse or a regular partner. The use of condoms by both men and women during sexual intercourse reduces the risk of contracting HIV. Table 12.9 shows the percentage of women and men age 15-49 who had sexual intercourse with a non-marital, non-cohabiting partner within the 12 months preceding the survey.

The table shows that one in five women and two in five men reported engaging in higher-risk sexual behaviour. Higher-risk sexual behaviour is most common among the youngest cohort of women and men. In fact, it is disturbing to note that half of women age 15-24 and more than four-fifths of men in the same age cohort engage in risky sexual behaviour. Among those who did engage in higher-risk sex, 28 percent of women and 45 percent of men age 15-49 used a condom during their higher-risk sex.

Higher-risk sex is especially common among women and men who have never married or who are currently divorced, separated, or widowed. For example, nearly all sexually active women who have never married engage in higher-risk sex, while only one-third of them used a condom during their last higher-risk sex. Residents of urban areas are also more likely than their rural counterparts to engage in higher-risk sexual behaviour. The percentage engaging in higher-risk sexual behaviour rises with the level of education. Nevertheless, as education level rises, there is a greater likelihood of respondents reporting using a condom during last higher-risk sex. Higher-risk sexual behaviour increases with increasing wealth quintile. Condom use at last higher-risk sex also increases with the level of household wealth.

Table 12.9 Higher-risk sex and condom use at last higher-risk sex among women and men age 15-49

Among women and men age 15-49 reporting sexual activity in the past 12 months, percentage who had sex with a non-marital, non-cohabiting partner (higher-risk sex) in the past 12 months, and among these women and men, percentage who say they used a condom the last time they had sex with a non-marital, non-cohabiting partner, by background characteristics, Ghana 2003

men age 25-39, never-married women and ever-married men, urban women and men, women and men residing in Greater Accra, highly educated women and men, and wealthier women and men.

Some of the major strategies for reducing HIV infection among young men and women is to delay the age of first sex, limit the number of sexual partners to one, and encourage and promote consistent and correct use of condoms. Young men and women are the target of most HIV/AIDS interventions aimed at sexual behavioural change. Some of these strategies and interventions seem to have some impact.

12.10 PAID SEX

Sex with commercial sex workers is associated with higher-risk sexual behaviour. According to a second-generation surveillance survey conducted in 2002 in Kumasi and Accra by The West African Project to combat AIDS and STI, HIV/AIDS prevalence among sex workers is 54 percent in Kumasi and 23 percent in Accra.

Table 12.11 shows the percentage of men age 15-49 reporting having had sex with a prostitute in the 12 months preceding the survey. About 2 percent of men reported sex with a prostitute in the last 12 months. Less than half of these men reported using a condom at last sex with a prostitute (data not shown).

12.11 SELF-REPORTING OF SEXUALLY TRANSMITTED INFECTIONS AND SYMPTOMS

There is a strong link between other sexually transmitted infections (STI) and HIV infection. It is believed that people having any other STI apart from HIV infection have a very high likelihood of being infected with HIV. STIs are therefore identified as co-factors in HIV transmission. One of the key interventions of the National Response on HIV/AIDS is to minimise STI transmission by improving the management of STI through strengthening symptomatic management of STIs in both government and private health institutions.

Table 12.12 shows the percentage of women and men who self-reported an STI and/or symptoms of an STI in the 12 months preceding the survey, among those who have ever had sex. Two percent of women and men report having had an STI in the 12 months preceding the survey. A higher percentage of women than men report abnormal genital discharge (7 and versus 3 percent, respectively). Three percent of women and 2 percent of men reported having a genital sore or ulcer.

12.12 STI TREATMENT-SEEKING BEHAVIOUR

Stigma and discrimination can discourage infected persons from seeking professional health care and lead some to resort to self-medication. Table 12.13 shows treatment-seeking behaviour among those who reported an STI or symptoms of an STI, by source of advice or treatment. Just over one-third of women and men sought care. About half (49 percent) of the men who reported an STI or symptoms of an STI sought advice or obtained medicine from a shop or pharmacy. Nearly one-third of men (31 percent) and half of women (44 percent) did not seek any advice or treatment.

12.13 SEXUAL BEHAVIOUR AMONG YOUNG WOMEN AND MEN

Promoting change in sexual behaviour is an important component of many HIV/AIDS prevention programmes. Those who are not yet sexually active or those who have recently made their sexual debut are thought to be more accepting of programmes focusing on behavioural changes. Subsequent tables in this chapter focus on young women and men age 15-24 and the sexual behaviours that affect their risk of exposure to HIV.

Table 12.13 Women and men seeking treatment for STIs

Percentage of women and men age 15-49 reporting a sexually transmitted infection (STI) or symptoms of an STI in the past 12 months who sought care, by source of treatment, Ghana 2003

Source of advice or treatment	Women	Men
Clinic/hospital/health professional[1]	36.5	34.9
Traditional healer	14.1	18.4
Advice or medicine from shop/pharmacy	25.9	49.3
Advice from friends/relatives	14.1	21.9
Advice or treatment from any source	56.2	69.3
No advice or treatment	43.8	30.7
Number with STI and/or symptoms of STI	400	145

Note: Symptoms of an STI are an abnormal genital discharge, a genital sore, or a gential ulcer.

One of the strategies for reducing the risk of contracting an STI is for young persons to delay the age at which they become sexually active. Table 12.14 shows the percentage of young people who have had sex by exact age 15 and 18, by background characteristics. More women than men have had first sex by age 15 and 18. Seven percent of women and 4 percent of men had sex by exact age 15. Forty-six percent of women and 27 percent of men first had sex by exact age 18. Women and men residing in rural areas have sex earlier than urban settlers. Variations by background characteristics are all greater among women than men. Young women in the Northern Region are most likely to initiate sex at an early age. In contrast, young women in Greater Accra are least likely to initiate sex at an early age. Age at first sex increases with educational attainment. Respondents in the two poorest wealth quintiles have first sex earlier than those in higher quintiles.

Table 12.14 Age at first sex among young women and men

Percentage of young women and men age 15-24 and 18-24 who have had sex by exact age 15 and 18, by background characteristics, Ghana 2003

Promoting the use of condoms is an important strategy in the fight against HIV/AIDS transmission. Knowing where to get a condom is therefore essential. Table 12.15 shows the percentage of young people age 15-24 who know at least one source for condoms. Young women and men are more likely to know a source of a male rather than a female condom. Two-thirds of women and four-fifths of men age 15-24 know a source for a male condom, while less than half of youths know a source for female

condom. Knowledge of a source is higher among youth age 20-24 than among those age 15-19. Knowledge of a condom source is also higher among sexually active never-married women and men. Urban women and men are more knowledgeable about a source of condoms. There are also regional variations in the knowledge of a source of condoms, with residents in the three northern regions less knowledgeable of a source than youths in the other regions. Knowledge of a source rises steadily and dramatically with level of education and wealth quintile.

Table 12.15 Knowledge of a source for condoms among young women and men

Percentage of young people age 15-24 who know at least one source of condoms, by background characteristics, Ghana 2003

Background characteristic	Women			Men

Note: The following sources are not considered sources for condoms in this table: church, friends, family members and home

Table 12.16 shows the percentage of young women and men who used a condom the first time they had sex. Twenty-two percent of young women and 37 percent of young men reported condom use at

first sex. Condom use at first sex is more common among women age 15-19 than among those age 20-24. Men age 20-24 are slightly more likely than men age 15-19 to use a condom at first sex. Condom use at first sex is more common among young women and men who have never married, those residing in the urban areas, and young women and men living in Greater Accra and the Volta Region. Condom use rises steadily and dramatically with increasing education and wealth quintile among both women and men.

Table 12.16 Condom use at first sex among young women and men

Among women and men age 15-24 who have ever had sex, percentage who used a condom the first time they had sex, by background characteristics, Ghana 2003

Table 12.18 shows the percentage of young women and men who had sexual relations with a non-marital, non-cohabiting partner, among those who were sexually active in the last 12 months, and the percentage who say they used a condom the last time they had sex with a non-marital, non-cohabiting partner. One in two young women (50 percent) and more than four in five young men (83 percent) age 15-24 who were sexually active engaged in higher-risk sexual behaviour, that is, they were sexually

active with a non-marital, non-cohabiting partner. Only 33 percent of women and 52 percent of men used a condom during their last higher-risk sexual intercourse.

<u>Table 12.18 Higher-risk sex and condom use at last higher-risk sex</u>

Among sexually active young women and men age 15-24, percentage who had sexual relations with a non-marital, non-cohabiting partner in the past 12 months, and among these women and men, percentage who say they used a condom the last time they had sex with a non-marital, non-cohabiting partner, by background characteristics, Ghana 2003

Figure 12.2 summarises data on the proportion of young women and men age 15-24 who fall into various risk categories for HIV. For example, 40 percent of young women and 61 percent of young men have never had sex, while 12 percent and 9 percent, respectively, have had sex but not in the 12 months

preceding the survey. Nine percent of women and 11 percent of men have had sex with only one partner in the 12 months preceding the survey and used a condom during the most recent sexual encounter. Thirty-eight percent of women and 14 percent of men had sex with only one partner but did not use condoms during the most recent sexual encounter. Less than 1 percent of women and about 3 percent of men had sex with more than one partner in the 12 months preceding the survey and used a condom at last sex. Perhaps the highest risk group is the 1 percent of women and 3 percent of men who had sex with more than one partner in the previous 12 months and did not use a condom during their most recent sex.

Figure 12.2 Abstinence, Being Faithful, and Using Condoms Among Women and Men Age 15-24

Note: Refers to partners in the 12 months prior to the survey
and condom use at most recent sexual encounter.

GDHS 2003

A practice that can contribute to the spread of HIV is sexual relations between young women and older men. To obtain information on age-discontinuities in sexual relationships, the 2003 GDHS asked sexually active women age 15-19 who had sex with a non-marital partner in the 12 months preceding the survey, whether the man was younger, about the same age, or older than them. If older, they were also asked if they thought he was less than 10 years older or 10 or more years older. Table 12.19 shows that only 5 percent of women age 15-19 who had non-marital sex in the 12 months before the survey had sexual intercourse with a man 10 or more years older than them. There is little variation by background characteristics of respondents.

12.14 ORPHANHOOD AND CHILDREN'S LIVING ARRANGEMENTS

To ascertain if there has been an upsurge in the number of orphans due to death of parents from HIV, the 2003 GDHS sought information on orphanhood and fostering. Table 12.20 shows the percent distribution of children under age 18 by children's living arrangements and survival status of parents, according to background characteristics.

Eighty-two percent of children under age 18 are living with one or both parents, 52 percent of children are living with both parents, 25 percent are living with their mother, and 5 percent are living with their father. Eighteen percent of children do not live with either parent, that is, they are fostered. Younger children, children living in rural areas, those residing in the three northern regions, and those from the lowest wealth quintile are more likely than other children to be living with both parents.

Table 12.19 Age discontinuity in sexual relationships

Among women age 15-19 who had nonmarital sex in the past 12 months, percentage who have had nonmarital sex with a man 10 or more years older than themselves, by background characteristics, Ghana 2003

Note: An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed. Figures in parentheses are based on 25-49 unweighted cases.

Table 12.20 also shows that 5 percent of children under 18 years are orphaned, that is, they have lost one or both of their parents, with 4 percent having lost their father, 1 percent having lost their mother, and half a percent having lost both parents. Orphanhood rises with child's age, from less than 1 percent among children under age 2 to 10 percent among those age 15-17. Children living in the Upper West Region are most likely to be orphaned (8 percent).

There has been little change in the percentage of young children fostered or orphaned over the last five years. For example, the percentage of children under 15 years who are fostered has remained unchanged at 13 percent between 1998 and 2003 (GSS and Macro, 1999).

It is generally believed that orphans are more likely to be disadvantaged than children whose parents are both living. To ascertain if this is the case, data from the 2003 GDHS was used to compare school attendance among children whose parents were both alive, children living or not living with at least one

parent, and children who had lost one or both parents. The results indicate that 81 percent of children age 10-14, whose parents are both alive and who are living with one or both parents are in school, compared with 65 percent of children who have lost both parents, with the ratio of school attendance among orphaned to non-orphaned children age 10-14, being 0.8 (data not shown).

13

This chapter presents information on the coverage of HIV testing, the prevalence of HIV, and the factors associated with HIV infection among eligible women and men. The 2003 GDHS is the sixth survey (the others being Dominican Republic, Mali, Zambia, Kenya and Burkina Faso) in the international DHS programme to include HIV testing, and the third only (after Kenya and Burkina Faso) to anonymously link the HIV results with key behavioural, social, and demographic factors. The HIV prevalence data provide important information to plan the national response, to evaluate programme impact, and to measure progress on the Ghana HIV/AIDS Strategic Framework: 2001-2005. The understanding of the prevalence of HIV in the population and the analysis of social, biological, and behavioural factors associated with HIV infection provide new insights into the HIV epidemic in Ghana that may enable more precisely targeted messages and interventions.

In Ghana, as in most of sub-Saharan Africa, national HIV prevalence estimates have been derived primarily from HIV sentinel surveillance (HSS) in pregnant women attending antenatal clinics. Currently, the national sentinel surveillance system consists of 30 sites of which 23 are urban and 7 are rural sites strategically located in 28 of the 110 districts, and covering all 10 regions of the country. Since 1992, for 12 weeks each year, pregnant women seeking antenatal care (ANC) for the first time and patients newly diagnosed with sexually transmitted infections (STIs) attending STI clinics in the sentinel sites were tested for HIV using an anonymously unlinked method and the results entered into a database, analysed, and reported by the National AIDS Control Programme (NACP) (Ghana Health Service, 2003d). The latest round of sentinel surveillance was conducted between September and November 2003, and overlapped two of the three months of the GDHS fieldwork.

The rate of HIV infection in pregnant women has been shown to be a reasonable proxy for the prevalance level in the combined male and female adult population (WHO and UNAIDS, 2000). However, there are a number of challenges in using sentinel surveillance estimates derived exclusively from pregnant women attending select antenatal clinics for estimating the HIV rate in the general adult population. The ANC data do not capture information on HIV prevalence in non-pregnant women, nor in women who either do not attend a clinic for pregnancy care or receive ANC at facilities not represented in the surveillance system. Pregnant women are also at a higher risk for HIV infection than women who may be avoiding both HIV and pregnancy through the use of condoms or women who are not sexually active and are therefore less likely to become pregnant or expose themselves to HIV. The rates among pregnant women have also been found to be much higher than male HIV prevalence rates. For example, a World Health Organisation study of four cities in sub-Saharan Africa shows higher risk overall in women compared with men (Buve et al., 2001).

Although the information from the ANC surveillance system has been very useful for monitoring trends in HIV levels, the inclusion of HIV testing in the GDHS offers the opportunity to better understand the magnitude and patterns of infection levels in the general reproductive-age population. The GDHS results are in turn expected to improve the calibration of annual sentinel surveillance data, so that trends in HIV infection can be more accurately measured in the intervals between general population surveys. In addition, the DHS data have the added advantage of providing behavioural data linked to HIV prevalence, which can be used to guide HIV prevention programmes.

13.1 COVERAGE OF HIV TESTING

Table 13.1 shows the percent distribution of women and men eligible for HIV testing by testing status, according to urban-rural residence and region. HIV tests were conducted for 89 percent of the 5,949 eligible women and 80 percent of the 5,345 eligible men. For both sexes combined, coverage was 85 percent, with rural residents more likely to be tested than their urban counterparts (87 and 81 percent, respectively). There were marked differences in HIV testing coverage by region. Coverage was highest in the Central Region where 93 percent of women and men were tested, and lowest in Greater Accra, where 76 percent of eligible women and men were tested. Coverage was higher among women than among men in every region, with the difference between women and men tested being widest in Greater Accra (84 and 65 percent, respectively) and narrowest in the Northern Region (86 and 85 percent, respectively).

Table 13.1 Coverage of HIV testing

Individuals who were not tested can be categorized into four groups based on the reason for nonresponse. Eight percent of eligible women and men refused testing when asked for informed consent by the health worker (Table 13.1). Five percent were absent for testing: 2 percent were interviewed in the survey, but were not at home when the health worker arrived for testing and were not found on callbacks; 3 percent were not at home for both the interview and testing. Two percent were missing test results for

some other reason, such as they were incapable of giving consent for testing, there was a mismatch between the questionnaire and the blood sample, or there was a technical problem in taking blood.

Refusal is the most important reason for non-response on the HIV testing component, with men nearly twice as likely to refuse testing as women (11 and 6 percent, respectively). Seven percent of men were absent for testing compared with 3 percent of women, with both women and men more likely to be absent for testing and never interviewed, than to have been interviewed but not tested.

The proportions falling into the four non-response categories vary by urban-rural residence, with urban coverage below rural coverage among both women and men in every category. The urban-rural differentials in coverage are most marked for refusal rates, which are 7 percent and 15 percent among urban women and men, respectively, and 5 percent and 8 percent for rural women and men, respectively.

Regionally, refusal is highest in the Eastern Region among both women (11 percent) and men (19 percent). Variation in refusal rates again accounts for much of the regional disparities. Refusal is also higher among both women and men in the Upper West Region (10 and 17 percent, respectively) and in Greater Accra (7 and 17 percent, respectively). For both women and men, absence is relatively high in Greater Accra and the Upper East.

Table 13.2 shows coverage rates for HIV testing by background characteristics. If knowledge of HIV status influenced participation in the testing, coverage would be expected to rise with age because HIV levels increase sharply with age before leveling off or declining at the older ages. In fact, the coverage rate for testing among women is consistent across all age groups (88 to 91 percent). Response rates are somewhat more variable by age among men (77 to 83 percent), but again they do not rise with age as would be expected if they were influenced by HIV status.

To further explore whether non-response might have had an impact on the HIV seroprevalence results, additional analysis was undertaken on the relationships between participation in the HIV testing and a number of other characteristics related to HIV risk. The descriptive tables examined in this analysis are included in Appendix A.

The variation in response rates with these measures indicate that coverage rates are not uniformly lower among those groups considered to be at higher risk for HIV (Tables A.3-A.6). However, there is some indication that some higher-risk groups may have lower response rates. Where response rates are lower for higher-risk groups, the pattern is more obvious for men than women. For example, response rates are slightly lower among divorced or separated men than among those currently in union, and among those who have ever had sex than among those who have never had sex. Similarly, men who sleep away from home—a characteristic assumed to be related to higher HIV risk—is not strongly related to lower coverage, with the exception of men who slept away more than five times in the past year, who have a slightly lower coverage.

The initial descriptive examination of HIV testing coverage levels provided little evidence of a consistent relationship between non-response rate and variables associated with higher HIV risk. Although further analysis is required, this analysis supports the conclusion that the GDHS prevalence rates are a reasonable measure of the actual levels of HIV prevalence in the population.

13.2　HIV PREVALENCE

13.2.1　HIV Prevalence by Socioeconomic Characteristics

Results from the 2003 GDHS indicate that 2 percent of Ghanaian adults are infected with HIV (Table 13.3).[1] HIV prevalence in women age 15-49 is nearly 3 percent, while for men 15-59, it is under 2 percent. This female-to-male ratio of 1.8 to 1 is higher than that found in most population-based studies in Africa. The high female-to-male ratio implies that young women are particularly vulnerable to HIV infection compared with young men. Prevalence among females is consistently higher than among males at all age groups except at age 40-44, where male prevalence is higher (Figure 13.1). The female-male gap is particularly large among women and men age 25-29, where women are nearly three and a half times as likely to be HIV positive as men. The peak prevalence among women is at age 35-39 (5 percent), while prevalence rises gradually with age among men to peak at age 40-44 (4 percent). These results compare favourably with the HSS and AIDS data available for Ghana.

Table 13.3 HIV prevalence by age

Percentage HIV positive among women 15-49 and men 15-59 who were tested, by age, Ghana 2003
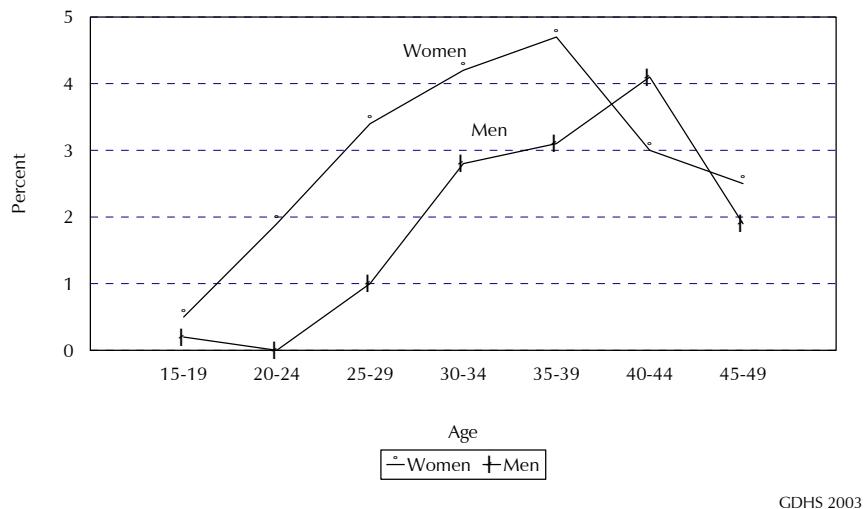

Age	Women		Men		Total	
	Percentage HIV positive	Number	Percentage HIV positive	Number	Percentage HIV positive	Number
15-19	0.5	1,035	0.2	1,035	0.3	2,070

Total age 15-59	na	na	1.6	4,469	na	na

na = Not applicable

Few HIV-infected children survive into their teenage years. As such, infected youth represent more recent cases of HIV infection and serve as an indicator of trends in both prevalence and incidence. The majority of HIV positive persons in the age group 15-24 are women, with less than half a percent among HIV positive men in the same age group. The overall prevalence in youth is under 2 percent. These prevalence levels will provide a baseline for measuring progress toward the goals underlined in the Ghana HIV/AIDS Strategic Framework in future surveys.

---

[1] The prevalence of HIV 2 was found to be 0.4 percent among women age 15-49 and 0.1 percent among men age 15-59, with an overall prevalence of 0.3. Prevalence in this chapter refers to the overall prevalence of HIV 1, HIV 2, and HIV 1/2.

Figure 13.1 HIV Prevalence by Age Group and Sex

GDHS 2003

As Table 13.4 shows, urban residents are only slightly more likely to be HIV positive than rural residents with the urban-rural difference among women slightly greater than among men.

The HIV epidemic shows regional variations. Prevalence is highest in the Eastern Region (4 percent), followed by the Western and Brong Ahafo regions (3 percent each). Prevalence is lowest in the Northern, Central, and Volta regions (1 percent each). Gender differences are apparent in all the regions.

Those who have completed primary and middle/JSS education have higher infection levels than those with either no education or at least secondary education. Work status is related to the HIV rate among both women and men, with prevalence twice as high among those currently working than those not currently working. Prevalence is highest among both women and men in the middle wealth quintile.

13.2.2 HIV Prevalence by Other Socio-demographic Characteristics

Marital status is related to HIV prevalence (Table 13.5). Prevalence is higher among widowed women (7 percent), followed closely by divorced or separated women (6 percent). Among men, prevalence is higher among divorced or separated men (6 percent). Women who report they have had sex but have never been in a union have a higher risk than men in the same category (3 percent and less than 1 percent, respectively). HIV infection among women and men who have never been in a union and have never had sex is almost non-existent, suggesting that non-sexual transmission of HIV is negligible.

Table 13.5 HIV prevalence by selected socio-demographic characteristics

Percentage HIV positive among women and men age 15-49 who were tested for HIV, by socio-demographic characteristics (marital status, pregnancy status for women, and mobility status for men), Ghana 2003

Total	2.7	5,097	1.5	4,047	2.2	9,144

Note: An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed. Total includes cases missing data on number of times slept away and whether away for more than one month.
na = Not applicable

Prevalence is slightly higher among women in a polygynous union than among women not in a polygynous union or not currently in union. Among men, prevalence is higher among those not in a polygynous union.

HIV prevalence among women who are pregnant is 4 percent, providing a useful benchmark to compare with rates for pregnant women tested during sentinel surveillance.

The survey results show that men who have slept away from home more than five times in the 12 months prior to the survey have higher HIV prevalence than men who have not slept away from home or have slept away from home less often. There is little difference in prevalence among men by length of time away from home.

13.2.3 HIV Prevalence by Sexual Risk Behaviour

Table 13.6 examines the prevalence of HIV infection by sexual behaviour indicators among respondents who have ever had sexual intercourse. In reviewing these results, it is important to remember that responses regarding sexual behaviour may be subject to reporting bias. Also, sexual behaviour in the 12 months preceding the survey may not adequately reflect lifetime sexual risk.

There is no clear relationship between age at sexual debut and HIV prevalence. Prevalence is highest among women who first had sexual intercourse before age 16 (5 percent). Prevalence is also relatively high among women whose age at sexual debut is 18-19 (4 percent). Among men, prevalence is highest among those whose age at sexual debut is 18-19 (3 percent).

There is no clear relationship between HIV prevalence and higher-risk sex, that is, sex with a non-marital or non-cohabiting partner. Women who have had higher-risk sex in the past 12 months are only slightly more likely to be HIV positive than women who have had no sex in the past 12 months. Men who have had sex but not higher-risk sex in the past 12 months are slightly more likely to be HIV positive than men who were not sexually active during the period.

Women who report having had sex with two partners and those who have had two higher-risk partners in the past 12 months are three times as likely to be HIV positive as women who have had only one partner or one higher-risk partner. Among men, no significant difference in prevalence can be detected by number of partners in the past 12 months, but those with one higher-risk partner are somewhat more likely to be HIV positive than men with two higher-risk partners.

HIV prevalence is substantially higher among men who paid for sex in the 12 months preceding the survey (7 percent) than among men who paid for sex prior to the past 12 months (3 percent) or who never paid for sex (2 percent).

There is little difference in HIV prevalence among those who used a condom at any time and those who used a condom at last sexual contact, in the 12 months preceding to the survey. However, women who did not use condom at last higher-risk sex in the 12 months preceding the survey are twice as likely to be HIV as women who used a condom. On the other hand, among men, prevalence is slightly lower among the former category of condom users than the latter category. Among men, those who used a condom at last paid sex are more likely to be HIV positive (5 percent) than those who did not use a condom at last paid sex (3 percent).

The discussion above suggests that there is no consistent relationship between HIV prevalence and sexual behavioural risk, particularly among men. However, more sophisticated analysis that is outside the scope of this report will be necessary to fully understand these relationships because they may be complicated by other factors such as age, residence, and educational status that are associated both with behavioural measures and HIV prevalence.

na = Not available

13.2.4 HIV Prevalence by Other Characteristics Related to HIV Risk

Table 13.7 shows the variation in HIV prevalence by various characteristics related to HIV risk among men and women who have ever had sex. As expected, women and men with history of a sexually transmitted infection (STI) or STI symptoms have higher rates of HIV infection than those with none.

Table 13.7 HIV prevalence by other indicators

Percentage HIV positive among women and men age 15-49 who ever had sex, by whether they had a sexually transmitted infection (STI), whether they had an HIV test, and reason for HIV test, Ghana 2003

Characteristic	Women		Men		Total	
	Percentage HIV positive	Number	Percentage HIV positive	Number	Percentage HIV positive	Number
Sexually transmitted infection						
Had STI or STI symptoms	4.9	360	2.2	137	4.2	496
No STI, no symptoms	3.0	3,946	1.9	2,840	2.6	6,786
HIV testing status						
Ever tested	4.6	487	1.4	337	3.3	824
Never tested	3.1	3,746	2.0	2,626	2.6	6,372
Reason for HIV testing						
Asked for test	6.4	150	2.0	149	4.2	299
Offered and accepted	5.2	201	0.0	96	3.5	297
Test required	3.7	68	0.0	87	1.6	155
Total	3.2	4,306	1.9	2,977	2.7	7,283

Note: Total includes 106 women and 17 men with missing information on HIV testing status, and 66 women and 4 men missing information on reason for HIV testing.

Women who have been tested for HIV in the past are more likely to be HIV positive than those who have never been tested. Among women who have ever had sex, the level of HIV infection is 5 percent among those who have ever been tested for HIV in the past and who know their status, compared with 3 percent among those who have never been tested. There is little difference in HIV prevalence and testing status among men.

HIV prevalence varies by reason for HIV testing, increasing from less than 2 percent among those who stated that the test was required, to more than 4 percent among those who asked for the test. The difference is more obvious among women than men, increasing from 4 percent among women for whom the test was required, to 5 percent among women who were offered the test and accepted, to more than 6 percent among women who asked for the test.

Although the individual's HIV status is associated with prior HIV testing, the above results indicate that many individuals who are HIV positive have not been tested. Nine out of ten of those infected with HIV (88 percent of infected women and 92 percent of infected men) do not know their HIV status, either because they were never tested or because they were tested and did not receive their results (Table 13.8). For women, 12 percent of those who are HIV positive have been tested and know the results for their last test, compared with 7 percent of those who are HIV negative. For men, 8 percent of those who are HIV positive know the results for their last test, compared with 7 percent of those who are HIV negative. It should be noted that testing for HIV may depend on a number of factors including access to testing facilities. Since HIV testing is not available universally in the country, where a person lives may influence the likelihood of being tested for HIV.

Table 13.8 HIV prevalence by prior HIV testing

Percent distribution of women and men age 15-49 by HIV testing status prior to the survey, according to whether positive or negative for HIV, Ghana 2003

	Women		Men

Total	100.0	100.0	100.0	100.0
Number	138	4,959	59	3,989

13.2.5 HIV Prevalence and Male Circumcision

Lack of circumcision is considered a risk factor for HIV infection, in part because of physiological differences that increase the susceptibility to HIV infection among uncircumcised men. The 2003 GDHS obtained information on male circumcision status, and these results can be used to examine the relationship between HIV prevalence and male circumcision.

As Table 13.9 shows, the vast majority of Ghanaian men (95 percent) are circumcised. However, the proportions circumcised vary by region, being markedly lower among men in the three northern regions and especially low in the Upper West Region (68 percent). The percent circumcised is also relatively lower among men who have no education (84 percent), among men in the lowest wealth quintile (82 percent), and among men who adhere to traditional or spiritualist religion (68 percent).

The number of men who are not circumcised in the population is rather small and therefore it is difficult to interpret the difference in prevalence between circumcised and uncircumcised men by background characteristics. Caution needs to be exercised when interpreting this table because both the numerators and the denominators on which these percentages are based are quite small. There is little difference in the HIV prevalence by circumcision status; however, some differences by background characteristics are noted.

Table 13.9 HIV prevalence among men by circumcision status

Among men age 15-59 who were tested for HIV, percentage who are circumcised and percentage HIV positive among circumcised and uncircumcised men, according to background characteristics, Ghana 2003

Total	95.3	4,469	1.6	4,258	1.4	210

Note: An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed. Figures in parentheses are based on 25-49 unweighted cases. Total includes 3 men for whom information on ethnicity is missing and 5 men with other religion or missing information on religion.

13.2.6 Prevalence among Couples

About 1,800 cohabiting couples were tested for HIV in the 2003 GDHS. Results shown in Table 13.10 indicate that, for the vast majority (96 percent) of cohabiting couples, both partners are HIV negative, while in only 1 percent of couples are both partners HIV positive. There is discordance in the

Table 13.10 HIV prevalence among couples

Among cohabiting couples both of whom were tested, percent distribution by HIV results, according to background characteristics, Ghana 2003

Total	1.0	1.6	1.5	95.8	100.0	1,792

Note: An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.

HIV positive status in under 2 percent of couples, where one partner is infected and the other is not. Couples where the woman is in the youngest age group (15-19), couples where the man is in the oldest age group (15-49), couples in a polygynous union, urban couples, couples living in Greater Accra, couples with primary education, and couples in the middle wealth quintile have slightly higher HIV prevalence than their counterparts in the other categories.

Discordance whereby the man is positive and the woman is not is more common than situations in which the woman is positive and the man is not. The fact that there are more couples that are discordant for HIV than couples that are both infected points to an unmet need for HIV prevention because the majority of these couples do not mutually know their HIV status. Couple-oriented voluntary counselling and testing (VCT) services, where partners (including those in polygynous marriages) go together and receive results together should be advocated for all VCT centers in Ghana.

13.3   DISTRIBUTION OF THE HIV BURDEN IN GHANA

An accurate estimation of HIV prevalence is necessary to assess the scope of the AIDS epidemic in Ghana and to track trends over time. Sentinel surveillance data from ANC clinics and from individuals seeking medical treatment for STIs have been the principal source of information on HIV prevalence in Ghana.

With the inclusion of HIV testing in the 2003 GDHS, Ghana has joined the first few countries in sub-Saharan Africa to expand the tools employed in monitoring the scope of the AIDS epidemic to include a nationally representative population-based survey. Ideally, the seroprevalence data from the GDHS survey will be examined and used to create a more accurate set of assumptions to use in estimating prevalence rates from future sentinel surveillance data. Indeed, UNAIDS and WHO suggest that population-based surveys "should definitely be used to calibrate the results of routine surveillance systems" (WHO and UNAIDS, 2000). The availability of population-based seroprevalence data from the 2003 GDHS clearly enhances the body of information available on the HIV/AIDS epidemic in Ghana.

ESTIMATES OF SAMPLING ERRORS

APPENDIX B

The estimates from a sample survey are affected by two types of errors: (1) non-sampling errors, and (2) sampling errors. Non-sampling errors are the results of mistakes made in implementing data collection and data processing, such as failure to locate and interview the correct household, misunderstanding of the questions on the part of either the interviewer or the respondent, and data entry errors. Although numerous efforts were made during the implementation of the 2003 Ghana Demographic and Health Survey (GDHS) to minimize this type of error, non-sampling errors are impossible to avoid and difficult to evaluate statistically.

Sampling errors, on the other hand, can be evaluated statistically. The sample of respondents selected in the 2003 GDHS is only one of many samples that could have been selected from the same population, using the same design and expected size. Each of these samples would yield results that differ somewhat from the results of the actual sample selected. Sampling errors are a measure of the variability between all possible samples. Although the degree of variability is not known exactly, it can be estimated from the survey results.

A sampling error is usually measured in terms of the *standard error* for a particular statistic (mean, percentage, etc.), which is the square root of the variance. The standard error can be used to calculate confidence intervals within which the true value for the population can reasonably be assumed to fall. For example, for any given statistic calculated from a sample survey, the value of that statistic will fall within a range of plus or minus two times the standard error of that statistic in 95 percent of all possible samples of identical size and design.

If the sample of respondents had been selected as a simple random sample, it would have been possible to use straightforward formulas for calculating sampling errors. However, the 2003 GDHS sample is the result of a multi-stage stratified design, and, consequently, it was necessary to use more complex formulae. The computer software used to calculate sampling errors for the 2003 GDHS is the ISSA Sampling Error Module. This module used the Taylor linearization method of variance estimation for survey estimates that are means or proportions. The Jackknife repeated replication method is used for variance estimation of more complex statistics such as fertility and mortality rates.

The Taylor linearization method treats any percentage or average as a ratio estimate, $r = y/x$, where y represents the total sample value for variable y, and x represents the total number of cases in the group or subgroup under consideration. The variance of r is computed using the formula given below, with the standard error being the square root of the variance:

$$SE^2(r) = var(r) = \frac{1-f}{x^2} \sum_{h=1}^{H} \left[\frac{m_h}{m_h-1} \left(\sum_{i=1}^{m_h} z_{hi}^2 - \frac{z_h^2}{m_h} \right) \right]$$

in which

$$z_{hi} = y_{hi} - rx_{hi} \text{, and } z_h = y_h - rx_h$$

where h represents the stratum which varies from 1 to H,
        m_h is the total number of clusters selected in the hth stratum,
        y_{hi} is the sum of the weighted values of variable y in the ith cluster in the hth stratum,
        x_{hi} is the sum of the weighted number of cases in the ith cluster in the hth stratum, and
        f is the overall sampling fraction, which is so small that it is ignored.

The Jackknife repeated replication method derives estimates of complex rates from each of several replications of the parent sample, and calculates standard errors for these estimates using simple formulae. Each replication considers *all but one* clusters in the calculation of the estimates. Pseudo-independent replications are thus created. In the 2003 GDHS, there were 412 non-empty clusters. Hence, 412 replications were created. The variance of a rate r is calculated as follows:

$$SE^2(r) = var(r) = \frac{1}{k(k-1)} \sum_{i=1}^{k} (r_i - r)^2$$

in which

$$r_i = kr - (k-1)r_{(i)}$$

where r is the estimate computed from the full sample of 412 clusters,
        $r_{(i)}$ is the estimate computed from the reduced sample of 411 clusters (i^{th} cluster excluded), and
        k is the total number of clusters.

In addition to the standard error, ISSA computes the design effect (DEFT) for each estimate, which is defined as the ratio between the standard error using the given sample design and the standard error that would result if a simple random sample had been used. A DEFT value of 1.0 indicates that the sample design is as efficient as a simple random sample, while a value greater than 1.0 indicates the increase in the sampling error due to the use of a more complex and less statistically efficient design. ISSA also computes the relative error and confidence limits for the estimates.

Sampling errors for the 2003 GDHS are calculated for selected variables considered to be of primary interest for woman's survey and for man's surveys, respectively. The results are presented in this appendix for the country as a whole, for urban and rural areas, and for each of the 10 regions. For each variable, the type of statistic (mean, proportion, or rate) and the base population are given in Table B.1. Tables B.2 to B.14 present the value of the statistic (R), its standard error (SE), the number of unweighted (N-UNWE) and weighted (N-WEIG) cases, the design effect (DEFT), the relative standard error (SE/R), and the 95 percent confidence limits (R±2SE), for each variable. The DEFT is considered undefined when the standard error considering simple random sample is zero (when the estimate is close to 0 or 1). In the case of the total fertility rate, the number of unweighted cases is not relevant, as there is no known unweighted value for woman-years of exposure to child-bearing.

The confidence interval (e.g., as calculated for *children ever born to women aged 40-49*) can be interpreted as follows: the overall average from the national sample is 5.493 and its standard error is 0.086. Therefore, to obtain the 95 percent confidence limits, one adds and subtracts twice the standard error to the sample estimate, i.e., 5.493±2×0.086. There is a high probability (95 percent) that the *true* average number of children ever born to all women aged 40 to 49 is between 5.321 and 5.664.

Sampling errors are analyzed for the national woman sample and for two separate groups of estimates: (1) means and proportions, and (2) complex demographic rates. The relative standard errors (SE/R) for the means and proportions range between 0.2 percent and 19.3 percent, with an average of 4.2

percent; the highest relative standard errors are for estimates of very low values (e.g., *currently using withdrawal*). If estimates of very low values (less than 10 percent) were removed, then the average drops to 2.5 percent. So in general, the relative standard error for most estimates for the country as a whole is small, except for estimates of very small proportions. The relative standard error for the total fertility rate is small, 2.9 percent. However, for the mortality rates, the average relative standard error for the seven 5-year period mortality rates is much higher, 8.1 percent.

There are differentials in the relative standard error for the estimates of sub-populations. For example, for the variable *want no more children*, the relative standard errors as a percent of the estimated mean for the whole country, and for the urban areas are 2.5 percent and 4.1 percent, respectively.

For the total sample, the value of the design effect (DEFT) averaged over all variables is 1.20, which means that due to multi-stage clustering of the sample the average standard error is increased by a factor of 1.20 over that in an equivalent simple random sample.

Table B.1 List of selected variables for sampling errors, Ghana 2003

Variable	Estimate	Base population
	WOMEN	
Urban residence	Proportion	All women 15-49
No education	Proportion	All women 15-49
With secondary education or higher	Proportion	All women 15-49
Never married (in union)	Proportion	All women 15-49
Currently married (in union)	Proportion	All women 15-49
Had first sex before 18	Proportion	All women 20-49
Children ever born	Mean	All women 15-49
Children ever born to women 40-49	Mean	All women 40-49
Children surviving	Mean	All women 15-49
Knowing any contraceptive method	Proportion	Currently married women 15-49
Knowing any modern contraceptive method	Proportion	Currently married women 15-49
Ever used any contraceptive method	Proportion	Currently married women 15-49
Currently using any method	Proportion	Currently married women 15-49
Currently using a modern method	Proportion	Currently married women 15-49
Currently female sterilisation	Proportion	Currently married women 15-49
Currently using pill	Proportion	Currently married women 15-49
Currently using IUD	Proportion	Currently married women 15-49
Currently using condom	Proportion	Currently married women 15-49
Currently using injectables	Proportion	Currently married women 15-49
Currently using periodic abstinence	Proportion	Currently married women 15-49
Currently using withdrawal	Proportion	Currently married women 15-49
Using public sector source	Proportion	Currently married women 15-49
Want no more children	Proportion	Currently married women 15-49
Want to delay at least 2 years	Proportion	Currently married women 15-49
Ideal number of children	Mean	All women 15-49
Mother received tetanus injection	Proportion	Births in last 5 years
Mother received medical care at birth	Proportion	Births in last 5 years
Child has diarrhoea in the last 2 weeks	Proportion	Children under 5
Child treated with ORS packets	Proportion	Children under 5 with diarrhoea in last 2 weeks
Consulted medical personnel	Proportion	Children 12-23 months
Child having health card, seen	Proportion	Children 12-23 months
Child received BCG vaccination	Proportion	Children 12-23 months
Child received DPT vaccination (3 doses)	Proportion	Children 12-23 months
Child received polio vaccination (3 doses)	Proportion	Children 12-23 months
Child received measles vaccination	Proportion	Children 12-23 months
Child fully immunised	Proportion	Children 12-23 months
Weight-for-height (-2 SD)	Proportion	Children under 5 who were measured
Height-for-age (-2 SD)	Proportion	Children under 5 who were measured
Weight-for-age (-2 SD)	Proportion	Children under 5 who were measured
Has heard of HIV/AIDS	Proportion	All women 15-49
Knows condoms reduce HIV/AIDS	Proportion	All women 15-49
Knows limiting partners reduce HIV/AIDS	Proportion	All women 15-49
Total fertility rate (last 3 years)	Rate	All women 15-49
Neonatal mortality rate (last 10 years)[1]	Rate	Number of births in last 5 (10 years)
Postneonatal mortality rate (last 10 years) [1]	Rate	Number of births in last 5 (10 years)
Infant mortality rate (last 10 years) [1]	Rate	Number of births in last 5 (10 years)
Child mortality rate (last 10 years) [1]	Rate	Number of births in last 5 (10 years)
Under-five mortality rate (last 10 years) [1]	Rate	Number of births in last 5 (10 years)
HIV prevalence	Proportion	All women 15-49 tested for HIV
	MEN	
Urban residence	Proportion	All men 15-59
No education	Proportion	All men 15-59
With secondary education or higher	Proportion	All men 15-59
Never married (in union)	Proportion	All men 15-59
Currently married (in union)	Proportion	All men 15-59
Had first sex before 18	Proportion	All men 20-59
Knowing any contraceptive method	Proportion	Currently married men 15-59
Knowing any modern contraceptive method	Proportion	Currently married men 15-59
Want no more children	Proportion	Currently married men 15-59
Want to delay at least 2 years	Proportion	Currently married men 15-59
Ideal number of children	Mean	All men 15-59
Has heard of HIV/AIDS	Proportion	All men 15-49
Knows condoms reduce HIV/AIDS	Proportion	All men 15-49
Knows limiting partners reduce HIV/AIDS	Proportion	All men 15-49
HIV prevalence (15-49)	Proportion	All men 15-49 tested for HIV
HIV prevalence (15-59)	Proportion	All men 15-59 tested for HIV

[1] 5 years for national sample and 10 years for regional sample.

Table C.2 Age distribution of eligible and interviewed women and men

De facto household population of women age 10-54 and men age 10-64, interviewed women age 15-49 and men age 15-59, and percentage of eligible women and men who were interviewed (weighted), by five-year age groups, Ghana 2003

| Age group | Household population of women age 10-54 | Interviewed women age 15-49 | | Percentage of eligible women interviewed |
		Number	Percent	
10-14	1,685	Na	na	na
15-19	1,191	1,128	20.2	94.6
20-24	1,053	1,006	18.0	95.5
25-29	981	944	16.9	96.2
30-34	821	797	14.3	97.0
25-39	756	712	12.7	94.2
40-44	577	557	10.0	96.6
45-49	465	445	8.0	95.8
50-54	492	Na	na	na
15-49	5,845	5,588	100.0	95.6

| Age group | Household population of men age 10-64 | Interviewed men age 15-59 | | Percentage of eligible men interviewed |
		Number	Percent	
10-14	1,907	Na	na	na
15-19	1,148	1,071	22.2	93.2
20-24	707	660	13.7	93.3
25-29	758	706	14.7	93.2
30-34	634	604	12.5	95.2
25-39	522	486	10.1	93.1
40-44	420	398	8.3	94.6
45-49	445	419	8.7	94.1
50-54	301	282	5.9	93.7
55-59	197	189	3.9	95.5
60-64	253	Na	na	na
15-59	5,134	4,814	100.0	93.8

Note: The de facto population includes all residents and non-residents who stayed in the household the night before the interview. Weights for both household population of women and men and interviewed women and men are household weights. Age is based on the household schedule.

na = Not applicable

Table C.3 Completeness of reporting

Percentage of observations missing information for selected demographic and health questions (weighted), Ghana 2003

Subject	Reference Group	Percentage with missing information	Number of cases
Birth date	Births in the 15 years preceding the survey		
Month Only		2.09	10,038
Month and Year		0.19	10,038
Age at death	Deceased children born in the 15 years preceding the survey	0.58	1,039
Age/date at first union[1]	Ever-married women age 15-49	0.43	4,075
Respondent's education	All women age 15-49	0.00	5,691
Diarrhoea in last 2 weeks	Living children age 0-59 months	2.27	3,340
Anthropometry	Living children age 0-59 months (from the household questionnaire)		
Height		5.22	3,597
Weight		5.04	3,597
Height or weight		5.49	3,597
Anaemia			
Children	All de facto living children 0-59 months	8.74	3,275
Women	All de facto women age 15-49	11.05	5,845

[1] Both year and age missing

Table C.4 Births by calendar years

Number of births, percentage with complete birth date, sex ratio at birth, and calendar year ratio by calendar year, according to living, dead, and total children (weighted), Ghana 2003

Calendar year	Number of births			Percentage with complete birth date[1]			Sex ratio at birth[2]			Calendar year ratio[3]

Hello, my name is (YOUR NAME) and I am from the Ghana Health Services and collaborating with the Ghana Statistical Service that is carrying out this health survey. .As part of this survey, we are studying anemia among women and children. Anemia is a serious health problem that results from poor nutrition. This survey will assist the government to develop programs to prevent and treat anemia.

We request that you (and all children born in 1998 or later) participate in the anemia testing part of this survey and give a few drops of blood from a finger. The test uses disposable sterile instruments that are clean and completely safe. The blood will be analyzed with new equipment and the results of the test will be given to you right after the blood is taken. The results will be kept confidential.

May I now ask that you (and NAME OF CHILD[REN]) participate in the anemia test. However, if you decide not to have the test done, it is your right and we will respect your decision. Now please tell me if you agree to have the test(s) done.

Note: In countries where some enumeration areas are higher than 1,000 meters, altitude information should be collected for each enumeration area higher than 1,000 meters so that the anemia estimates can be adjusted appropriately.

50	CHECK 47 AND 48:

NUMBER OF PERSONS WITH HEMOGLOBIN LEVEL BELOW THE CUTOFF POINT*

ONE OR MORE ☐   NONE ☐

GIVE EACH WOMAN/PARENT/RESPONSIBLE ADULT RESULT OF HEMOGLOBIN MEASUREMENT AND CONTINUE WITH 51.**   GIVE EACH WOMAN/PARENT/RESPONSIBLE ADULT RESULT OF HEMOGLOBIN MEASUREMENT AND END HOUSEHOLD INTERVIEW.

51	We detected a low level of hemoglobin in (your blood/the blood of NAME OF CHILD(REN)). This indicates that (you/NAME OF CHILD(REN)) have developed severe anemia, which is a serious health problem. We would like to inform the doctor at _____ about (your condition/the condition of NAME OF CHILD(REN)). This will assist you in obtaining appropriate treatment for the condition. Do you agree that the information about the level of hemoglobin in (your blood/the blood of NAME OF CHILD(REN)) may be given to the doctor?

CONSENT STATEMENT

Hello, my name is _____. I'm from the Ghana Health Services and collaborating with the Ghana Statistical Services. As part of this survey, we are studying HIV among women and men. As you know, HIV is the virus that causes AIDS. The government is trying to find out how common HIV is, so that they can develop programs to prevent HIV and care for those who have it.

We request that you participate in this test by giving a few drops of blood from a finger. For this test, I will use clean, sterile instruments that are completely safe. Blood will be tested later in the laboratory.

To ensure the confidentiality of this test result, no individual names will be attached to the blood sample; therefore, we will not be able to give you the result of your test and no one will be able to trace the test back to you. If you want to know whether you have HIV, I can tell you where you can go to get tested.

Do you have any questions?

I hope you will agree to participate in the HIV testing. But if you decide not to have the test done, it is your right and I will respect your decision.

Will you accept to participate in the HIV test? GO BACK TO COLUMN (59). CIRCLE THE APPROPRIATE CODE AND SIGN.

IF RESPONDENT IS AGE 15-17, ASK PARENT/GUARDIAN: Now, will you tell me if you accept for (NAME OF YOUTH) to participate in the HIV test? GO TO COLUMN (58). CIRCLE THE APPROPRIATE CODE AND SIGN. IF PARENT AGREES, READ THE PRECEDING PARAGRAPHS TO YOUTH FOR HIS/HER CONSENT AND RECORD IN COL. (59).

NOTE FOR THE INTERVIEWER:
THE RESPONDENT HAS THE RIGHT TO REFUSE THE HIV TEST, AND THEREFORE SHOULD NOT BE FORCED.

INTRODUCTION AND CONSENT

INFORMED CONSENT
Hello. My name is _____ and I am working with the Ghana Statistical Service. We are conducting a national survey about the health of women, men and children. We would very much appreciate your participation in this survey. I would like to ask you about your health (and the health of your children). This information will help the government to plan health services. The survey usually takes between 20 and 45 minutes to complete. Whatever information you provide will be kept strictly confidential and will not be shown to other persons. Participation in this survey is voluntary and you can choose not to answer any individual question or all of the questions. However, we hope that you will participate in this survey since your views are important. At this time, do you want to ask me anything about the survey? May I begin the interview now? Signature of interviewer: _____   Date: _____ RESPONDENT AGREES TO BE INTERVIEWED 1   RESPONDENT DOES NOT AGREE TO BE INTERVIEWED .... 2 ⟶END

INFORMED CONSENT

Hello. My name is _____ and I am working with the Ghana Statistical Service. We are conducting a national survey about the health of women, men and children. We would very much appreciate your participation in this survey. I would like to ask you some questions about yourself and your family. This information will help the government to plan health services. The survey usually takes between 15 and 30 minutes to complete. Whatever information you provide will be kept strictly confidential and will not be shown to other persons.

Participation in this survey is voluntary and you can choose not to answer any individual question or all of the questions. However, we hope that you will participate in this survey since your views are important.

At this time, do you want to ask me anything about the survey?
May I begin the interview now?

Signature of interviewer: _____   Date: _____

RESPONDENT AGREES TO BE INTERVIEWED 1   RESPONDENT DOES NOT AGREE TO BE INTERVIEWED.....2 ⟶END

NO.	QUESTIONS AND FILTERS	CODING CATEGORIES	SKIP
101	RECORD THE TIME.	HOUR…………………………. ☐☐ MINUTES ……………………… ☐☐	
102	First I would like to ask some questions about you and your household. For most of the time until you were 12 years old, did you live in a city, in a town, or in the village	CITY...1 TOWN...2 VILLAGE...3

<u>World Summit for Children Indicators, Ghana 2003</u>

Childhood mortality	Infant mortality rate (per 1,000 live births)	64 per 1,000
	Under-five mortality rate (per 1,000 live births)	111 per 1,000
Childhood undernutrition	Percent stunted (children under 5 years)	29.9
	Percent wasted (children under 5 years)	7.1
	Percent underweight (children under 5 years)	22.1
Clean water supply	Percent of households with safe water supply[1]	67.2
Sanitary excreta disposal	Percent of households with flush toilets, pit toilet/latrine	78.1
Basic education	Proportion of children reaching grade 5[2]	98.1
	Net primary school attendance rate[2]	60.4
	Proportion of children entering primary school[2]	18.0
Family planning	Contraceptive prevalence rate (any method, currently married women)	25.2
	Contraceptive prevalence rate (any method, all women)	20.7
Antenatal care	Percent of women who received antenatal care from a health professional[3]	91.9
Delivery care	Percent of births in the 5 years preceding the survey attended by a health professional	47.1
Low birth weight	Percent of births in the 5 years preceding the survey at low birth weight[4]	8.5
Iodised salt intake	Percent of households that use iodised salt[5]	25.4
Vitamin A supplements	Percent of children age 6-59 months who received a vitamin A dose in the 6 months preceding the survey	78.4
	Percent of women age 15-49 who received a vitamin A dose in the 2 months after delivery[3]	43.0
Night blindness	Percent of women 15-49 who suffered from night blindness during pregnancy[3]	7.7
Exclusive breastfeeding	Percent of youngest children under 6 months who are exclusively breastfed	53.4
Continued breastfeeding	Percent of children age 12-15 months still breastfeeding	94.6
	Percent of children age 20-23 months still breastfeeding	62.9
Timely complementary feeding	Percent of youngest children age 6-9 months receiving breast milk and complementary foods	62.2
Vaccinations	Percent of children age 12-23 months with tuberculosis vaccination	91.1
	Percent of children age 12-23 months with at least 3 DPT vaccinations	79.5
	Percent of children age 12-23 months with at least 3 polio vaccinations	79.2
	Percent of children age 12-23 months with measles vaccination	83.2
	Percent of mothers who received at least 2 tetanus toxoid vaccinations during pregnancy[3]	50.4
Oral rehydration therapy (ORT)	Percent of children age 0-59 months with diarrhoea in the 2 weeks preceding the survey who received oral rehydration salts (ORS) or recommended home fluids (RHF)	46.4
Home management of diarrhoea	Percent of children age 0-59 months with diarrhoea in the 2 weeks preceding the interview who took more fluids than usual and continued eating somewhat less, the same or more food	24.9
Treatment of ARI	Percent of children age 0-59 months with acute respiratory infection (ARI) in the 2 weeks preceding the survey who were taken to a health provider	44.0
Birth registration	Percent of births with notification form	45.6
Children in especially difficult situations	Percent of children under age 15 with at least one parent dead[2]	16.3
	Percent of children under age 15 not living with either parent[2]	6.6
Treatment of illness	Percent of children age 0-59 months with diarrhoea, fever, and/or ARI in the two weeks preceding the survey who were taken to a health provider	38.8
Malaria treatment	Percent of children age 0-59 months with a fever in the 2 weeks preceding the survey who were treated with an anti-malarial drug	62.8
HIV/AIDS	Percent of women age 15-49 who correctly stated 2 ways of avoiding HIV infection[6]	68.9
	Percent of women age 15-49 who correctly identified 2 misconceptions about HIV/AIDS[7]	46.4
	Percent of women age 15-49 who believe that AIDS can be transmitted from mother to child during pregnancy, delivery and breastfeeding	65.0
	Percent of women age 15-49 who believe that a female teacher with the AIDS virus should not be allowed to continue teaching in the school	57.8
	Percent of women age 15-49 who know of a place to get tested for the AIDS virus	54.1
	Percent of women age 15-49 who have been tested for the AIDS virus	9.9

[1] Piped water, protected well water, or rainwater (not spring water)
[2] Excludes children with parental status missing
[3] For the last live birth in the five years preceding the survey
[4] For children without a reported birth weight, the proportion with low birth weight is assumed to be the same as the proportion with low birth weight in each birth size category among children who have a reported birth weight.
[5] 15 parts per million or more, among all households
[6] Having sex with only one partner who has no other partners and using a condom every time they have sex
[7] They say that AIDS cannot be transmitted through mosquito bites and that a healthy-looking person can have the AIDS virus.
