Cambodia Demographic and Health Survey 2005

National Institute of Public Health and National Institute of Statistics
Phnom Penh, Cambodia

ORC Macro
Calverton, Maryland, USA

December 2006

The analysis and preparation of this report on the Cambodia Demographic and Health Survey was achieved through the joint efforts of:

Darith Hor, NIS/MoP
Sovanratnak Sao, DGH/MoH
Vonthanak Saphonn, NIPH/MoH
Kia Reinis, ORC Macro
Keith Purvis, ORC Macro
Kaye Mitchell, ORC Macro
Bernard Barrère, ORC Macro
Ruilin Ren, ORC Macro
Rathavuth Hong, ORC Macro
Noah Bartlett, ORC Macro
Kiersten Johnson, ORC Macro
Joy Fishel, ORC Macro
Sri Poedjastoeti, ORC Macro
Monica Kothari, ORC Macro
Erica Nybro, ORC Macro
Andrew Inglis, ORC Macro
Sidney Moore, ORC Macro
John Chang, ORC Macro

See Appendix D for a list of contributors to the implementation of the CDHS.

The 2005 Cambodia Demographic and Health Survey (2005 CDHS) is part of the worldwide MEASURE DHS project which is funded by the United States Agency for International Development (USAID). The opinions expressed herein are those of the authors and do not necessarily reflect the views of USAID.

Additional information about the 2005 CDHS may be obtained from the National Institute of Public Health (#2, Kim Il Sung Blvd, Phnom Penh, Cambodia. Telephone: 855-23-880345, Fax: 855-23-880346, Email: usa@camnet.com.kh) or National Institute of Statistics (#386, Monivong Blvd, Phnom Penh, Cambodia. Telephone/Fax: 855-23-213-650, Email: hdarith@nis.gov.kh). Additional information about the DHS project may be obtained from ORC Macro, 11785 Beltsville Drive, Calverton, MD 20705 USA; Telephone: 301-572-0200, Fax: 301-572-0999, E-mail: reports@orcmacro.com, Internet: <http://www.measuredhs.com>.

TABLES AND FIGURES	ix
FOREWORD	xvii
ACKNOWLEDGMENTS	xix
SUMMARY OF FINDINGS	xxiii
CHAPTER 1 INTRODUCTION	
1.1 Geodemography, History, And Economy	1
1.2 Health Status And Policy	2
1.3 Objective and Survey Organization	3
1.4 Sample Design	3
1.5 Questionnaires.....	5
1.6 Training and Fieldwork	6
1.7 Data Processing.....	8
1.8 Sample Coverage	8
CHAPTER 2 HOUSEHOLD POPULATION AND HOUSING CHARACTERISTICS	
2.1 Characteristics of the Household Population	9
2.2 Education of the Household Population	11
2.3 Housing Characteristics	17
2.4 Household Possessions.....	22
2.5 Household Wealth.....	22
2.6 Birth Registration.....	24
CHAPTER 3 UTILIZATION OF HEALTH SERVICES FOR ACCIDENT, ILLNESS, OR INJURY	
3.1 Accidental Death or Injury	27
3.2 Physical Impairment.....	30
3.3 Prevalence and Severity of Illness or Injury	31
3.4 Treatment Sought for Illness or Injury	32
3.5 Utilization of Health Care Facilities	34
3.6 Cost for Health Care	35
CHAPTER 4 RESPONDENT CHARACTERISTICS	
4.1 Characteristics of Survey Respondents.....	41
4.2 Educational Attainment and Literacy	43
4.3 Access to Mass Media	47
4.4 Employment	49
4.5 Knowledge and attitudes concerning tuberculosis.....	56
4.6 Use of Tobacco.....	58

CHAPTER 5	FERTILITY	
5.1	Current Fertility Levels and Differentials	61
5.2	Fertility Trends	63
5.3	Children Ever Born and Living.....	66
5.4	Birth Intervals.....	67
5.5	Age at First Birth.....	69
5.6	Teenage Pregnancy and Motherhood.....	70
CHAPTER 6	PRACTICE OF ABORTION	
6.1	Number of Induced Abortions.....	73
6.2	Abortion in the Past Five Years	75
CHAPTER 7	FAMILY PLANNING	
7.1	Knowledge of Contraceptive Methods.....	79
7.2	Ever Use of Contraceptive Methods	81
7.3	Current Use of Contraceptive Methods	82
7.4	Number of Children at First Use of Contraception.....	85
7.5	Use of Social Marketing Brands	85
7.6	Knowledge of Fertile Period	86
7.7	Timing of Sterilization	87
7.8	Source of Family Planning Methods	87
7.9	Cost of Family Planning Methods	89
7.10	Informed Choice	89
7.11	Future Use of Contraception	91
7.12	Reasons for Not Intending to Use a Contraceptive Method in the Future.....	91
7.13	Preferred Method of Contraception for Future Use	92
7.14	Exposure to Family Planning Messages	92
7.15	Contact of Nonusers with Family Planning Providers	93
7.16	Husband's Knowledge of Wife's Use of Contraception.....	95
CHAPTER 8	OTHER PROXIMATE DETERMINANTS OF FERTILITY	
8.1	Marital Status	97
8.2	Age at First Marriage	98
8.3	Age at First Sexual Intercourse.....	100
8.4	Recent Sexual Activity	103
8.5	Postpartum Amenorrhea, Abstinence, and Insusceptibility.....	106
8.6	Termination of Exposure to Pregnancy	108
CHAPTER 9	FERTILITY PREFERENCES	
9.1	Desire for More Children	109
9.2	Need for Family Planning Services.....	111
9.3	Ideal Family Size	113
9.4	Fertility Planning	114

CHAPTER 10	ADULT AND MATERNAL MORTALITY	
10.1	Data Quality Issues	117
10.2	Adult Mortality	118
10.3	Maternal Mortality	119
CHAPTER 11	INFANT AND CHILD MORTALITY	
11.1	Assessment of Data Quality	121
11.2	Levels and Trends in Childhood Mortality	122
11.3	Socioeconomic Differentials in Childhood Mortality	125
11.4	Demographic Differentials in Mortality	127
11.5	High-Risk Fertility Behavior	128
CHAPTER 12	CAUSES OF DEATH AMONG INFANTS AND YOUNG CHILDREN	
12.1	Introduction	131
12.2	Cause of Death Reported by the Mother	131
12.3	Symptoms Prior to Death	133
12.4	Possible Cause of Death on the Basis of Symptoms	133
CHAPTER 13	MATERNAL HEALTH	
13.1	Antenatal Care	137
13.2	Childbirth and Delivery	143
13.3	Postnatal Care and Practices	146
13.4	Perceived Problems in Accessing Women’s Health Care	148
CHAPTER 14	CHILD HEALTH	
14.1	Child’s Size at Birth	151
14.2	Immunization of Children	153
14.3	Acute Respiratory Infection	155
14.4	Fever	157
14.5	Diarrhea	159
14.6	Feeding Practices	161
14.7	Knowledge of ORS Packets	163
14.8	Stool Disposal	163
CHAPTER 15	NUTRITION OF CHILDREN AND WOMEN	
15.1	Nutritional Status of Children	165
15.2	Initiation of Breastfeeding	169
15.3	Breastfeeding Status by Age	171
15.4	Duration and Frequency of Breastfeeding	173
15.5	Types of Complementary Foods	175
15.6	Infant and Young Child Feeding (IYCF) Practices	176
15.7	Prevalence of Anemia in Children	178
15.8	Micronutrient Intake among Children	180
15.9	Use of Iodized Salt	182

15.10	Nutritional Status of Women	183
15.11	Foods Consumed by Mothers.....	186
15.12	Prevalence of Anemia in Women.....	187
15.13	Micronutrient Intake among Mothers	189
CHAPTER 16	MALARIA	
16.1	Introduction	191
16.2	Malaria Prevention	191
16.3	Malaria Diagnosis and Treatment	195
CHAPTER 17	HIV/AIDS-RELATED KNOWLEDGE, ATTITUDES, AND BEHAVIOR	
17.1	Knowledge of HIV/AIDS and of Transmission and Prevention Methods.....	197
17.1.1	Awareness of AIDS	197
17.1.2	HIV Prevention Methods	197
17.1.3	Knowledge about Transmission.....	200
17.1.4	Knowledge of Mother-to-Child Transmission.....	203
17.2	Stigma Associated with AIDS and Attitudes Related to HIV/AIDS	205
17.3	Attitudes towards Negotiating Safer Sex and Educating Youth about Condom Use	208
17.4	Higher-Risk Sex	211
17.4.1	Multiple Sexual Partners and Higher-Risk Sex	211
17.4.2	Paid Sex	214
17.5	Testing for HIV	216
17.6	Reports of Recent Sexually Transmitted Infections	221
17.7	Injections.....	223
17.8	HIV/AIDS-Related Knowledge and Behavior Among Youth	226
17.8.1	Knowledge about HIV/AIDS and Source for Condoms	226
17.8.2	Age at First Sex and Condom Use at First Sexual Intercourse.....	227
17.8.3	Recent Sexual Activity.....	231
17.8.4	Higher-Risk Sex	233
17.8.5	Drunkenness during Sexual Intercourse	235
17.8.6	HIV Testing.....	237
CHAPTER 18	HIV PREVALENCE AND ASSOCIATED FACTORS	
18.1	HIV Testing Protocol.....	239
18.2	Coverage of HIV Testing in the CDHS.....	241
18.3	HIV Prevalence.....	245
18.4	HIV Prevalence Among Youth.....	252
18.5	HIV Prevalence by Other Characteristics Related to HIV Risk.....	254
18.6	HIV Prevalence Among Couples	255
CHAPTER 19	CHILDREN AT RISK	
19.1	Orphanhood and Children’s Living Arrangements.....	257
19.2	School Attendance.....	258
19.3	Basic Material Needs	259
19.4	Separation of Siblings.....	260

19.5	Succession Planning.....	261
19.6	Dispossession of Property	263
CHAPTER 20 WOMEN'S STATUS AND EMPOWERMENT		
20.1	Marriage Patterns.....	265
20.2	Interspousal Communication	268
20.3	Decisionmaking within Households	269
20.4	Attitudes toward Gender Roles	271
20.5	Support from Birth Family.....	276
20.6	Financial Empowerment	276
20.7	Involvement with Civil Society	278
CHAPTER 21 DOMESTIC VIOLENCE		
21.1	Approach to Violence Measurement.....	284
21.2	Women's Experience of Violence since Age 15 and Recent Violence in the 12 Months Preceding the Survey.....	285
21.3	Violence during Pregnancy	287
21.4	Marital Control	288
21.5	Interspousal Violence.....	290
21.6	Experience of Forced Sex at Sexual Initiation	297
21.7	Help-Seeking Behavior by Women Who Have Experienced Violence.....	297
REFERENCES		299
APPENDIX A SAMPLE IMPLEMENTATION		301
APPENDIX B ESTIMATES OF SAMPLING ERRORS.....		319
APPENDIX C DATA QUALITY TABLES		345
APPENDIX D PERSONS INVOLVED IN THE 2005 CAMBODIA DEMOGRAPHIC AND HEALTH SURVEY.....		351
APPENDIX E QUESTIONNAIRES		355

TABLES AND FIGURES

	Page
CHAPTER 1	INTRODUCTION
Table 1.1	Results of the household and individual interviews.....8
Figure 1.1	Implementation of Survey Instruments and Modules.....5
CHAPTER 2	HOUSEHOLD POPULATION AND HOUSING CHARACTERISTICS
Table 2.1	Household population by age, sex, and residence.....10
Table 2.2	Population by age according to selected sources.....11
Table 2.3	Household composition.....11
Table 2.4	Educational attainment of household population.....12
Table 2.5	School attendance ratios.....14
Table 2.6	Grade repetition and dropout rates.....16
Table 2.7	Household drinking water.....18
Table 2.8	Household sanitation facilities.....20
Table 2.9	Housing characteristics.....21
Table 2.10	Household possessions.....22
Table 2.11	Wealth quintiles.....24
Table 2.12	Birth registration of children under age five.....25
Figure 2.1	Population pyramid.....10
Figure 2.2	Age-specific attendance rates.....15
CHAPTER 3	UTILIZATION OF HEALTH SERVICES FOR ACCIDENT, ILLNESS, OR INJURY
Table 3.1	Injury or death in an accident.....28
Table 3.2	Injury and death in an accident by type of accident.....29
Table 3.3	Physical impairment.....30
Table 3.4	Prevalence and severity of illness or injury in previous 30 days.....32
Table 3.5	Percentage of ill or injured population who sought treatment.....33
Table 3.6	Percentage of ill or injured population who sought treatment.....34
Table 3.7	Distribution of cost for health care.....36
Table 3.8	Expenditures for health care.....37
Table 3.9	Source of money spent on health care.....39
Figure 3.1	Percentage of household members ill or injured seeking treatment by order of treatment and sector of health care.....35
CHAPTER 4	RESPONDENT CHARACTERISTICS
Table 4.1	Background characteristics of respondents.....42
Table 4.2.1	Educational attainment: women.....44

Table 4.2.2	Educational attainment: men	45
Table 4.3	Literacy: women	46
Table 4.4.1	Exposure to mass media: women	47
Table 4.4.2	Exposure to mass media: men	49
Table 4.5.1	Employment status: women	50

Table 7.16	Exposure to family planning messages	93
Table 7.17	Contact of nonusers with family planning providers	94
Table 7.18	Husband/partner's knowledge of women's use of contraception	95

CHAPTER 8 OTHER PROXIMATE DETERMINANTS OF FERTILITY

Table 8.1	Current marital status.....	97
Table 8.2	Age at first marriage	98
Table 8.3.1	Median age at first marriage: women	99
Table 8.3.2	Median age at first marriage: men.....	100
Table 8.4	Age at first sexual intercourse	101
Table 8.5.1	Median age at first sexual intercourse: women.....	102
Table 8.5.2	Median age at first sexual intercourse: men.....	103
Table 8.6.1	Recent sexual activity: women	104
Table 8.6.2	Recent sexual activity: men.....	105
Table 8.7	Postpartum amenorrhea, abstinence and insusceptibility.....	106
Table 8.8	Median duration of amenorrhea, postpartum abstinence and postpartum insusceptibility.....	107
Table 8.9	Menopause.....	108

CHAPTER 9 FERTILITY PREFERENCES

Table 9.1	Fertility preferences by number of living children	109
Table 9.2	Desire to limit childbearing	110
Table 9.3	Need and demand for family planning among currently married women ...	112
Table 9.4	Ideal number of children	113
Table 9.5	Mean ideal number of children.....	114
Table 9.6	Fertility planning status.....	115
Table 9.7	Wanted fertility rates.....	116

CHAPTER 10 ADULT AND MATERNAL MORTALITY

Table 10.1	Data on siblings	117
Table 10.2	Sibship size and sex ratio of siblings	118
Table 10.3	Adult mortality rates.....	119
Table 10.4	Direct estimates of maternal mortality.....	120

CHAPTER 11 INFANT AND CHILD MORTALITY

Table 11.1	Early childhood mortality rates	122
Table 11.2	Early childhood mortality rates by socioeconomic characteristics.....	126
Table 11.3	Early childhood mortality rates by demographic characteristics.....	127
Table 11.4	High-risk fertility behavior	129
Figure 11.1	Trends in childhood mortality, 2000 and 2005 CDHS	123

Figure 11.2	Trends in infant mortality	124
Figure 11.3	Trends in child mortality	124
Figure 11.4	Trends in under-five mortality	125
Figure 11.5	Infant mortality by mother's background characteristics	126
Figure 11.6	Infant mortality by selected demographic characteristics	128

CHAPTER 12 CAUSES OF DEATH AMONG INFANTS AND YOUNG CHILDREN

Table 12.1	Causes of death among infants and young children	131
Table 12.2	Infant and child deaths diagnosed by a health worker	132
Table 12.3	Symptoms during illness that led to death	133
Table 12.4	Possible diagnosis established from symptoms	134
Table 12.5	Multiple diagnoses	135

CHAPTER 13 MATERNAL HEALTH

Table 13.1	Antenatal care	138
Table 13.2	Number of antenatal care visits and timing of first visit	139
Table 13.3	Components of antenatal care	140
Table 13.4	Tetanus toxoid injections	142
Table 13.5	Place of delivery	144
Table 13.6	Assistance during delivery	145
Table 13.7	Timing of first postnatal checkup	147
Table 13.8	Type of provider of first postnatal checkup	148
Table 13.9	Problems in accessing health care	149

CHAPTER 14 CHILD HEALTH

Table 14.1	Child's weight and size at birth	152
Table 14.2	Vaccinations by source of information	153
Table 14.3	Vaccinations by background characteristics	154
Table 14.4	Prevalence and treatment of symptoms of ARI	156
Table 14.5	Prevalence and treatment of fever	158
Table 14.6	Prevalence of diarrhea	159
Table 14.7	Diarrhea treatment	160
Table 14.8	Feeding practices during diarrhea	162
Table 14.9	Knowledge of ORS packets or pre-packaged liquids	163
Table 14.10	Disposal of children's stools	164
Figure 14.1	Trends in vaccination coverage by 12 months of age (among children 12-23 months)	155

CHAPTER 15 NUTRITION OF CHILDREN AND WOMEN

Table 15.1	Nutritional status of children	167
Table 15.2	Initial breastfeeding	170
Table 15.3	Breastfeeding status by age	172
Table 15.4	Median duration and frequency of breastfeeding	174
Table 15.5	Foods and liquids consumed by children in the day or night preceding the interview	175

Table 15.6	Infant and young child feeding (IYCF) practices	177
Table 15.7	Prevalence of anemia in children	179
Table 15.8	Micronutrient intake among children	181
Table 15.9	Iodization of household salt	183
Table 15.10	Nutritional status of women	185
Table 15.11	Foods consumed by mothers in the day or night preceding the interview.....	187
Table 15.12	Prevalence of anemia in women	188
Table 15.13	Micronutrient intake among mothers	190
Figure 15.1	Nutritional status of children by age	168
Figure 15.2	Trends in nutritional status of children under five years	169
Figure 15.3	Among last-born children born in the five years preceding the survey who ever received a prelacteal liquid, the percentage who received various types of liquids.....	171
Figure 15.4	Infant feeding practices by age	173
Figure 15.5	Infant and young child feeding (IYCF) practices	178
Figure 15.6	Trends in anemia status among children age 6-59 months	180
Figure 15.7	Trends in nutritional status among women age 15-49	186
Figure 15.8	Trends in anemia status among women age 15-49.....	189

CHAPTER 16 MALARIA

Table 16.1	Household possession of mosquito nets	192
Table 16.2	Use of mosquito nets by children	193
Table 16.3	Use of mosquito nets by women	195
Table 16.4	Prevalence and prompt treatment of children with fever	196

CHAPTER 17 HIV/AIDS-RELATED KNOWLEDGE, ATTITUDES, AND BEHAVIOR

Table 17.1	Knowledge of AIDS.....	197
Table 17.2	Knowledge of HIV prevention methods.....	198
Table 17.3.1	Comprehensive knowledge about AIDS: women	201
Table 17.3.2	Comprehensive knowledge about AIDS: men	202
Table 17.4	Knowledge of prevention of mother-to-child transmission of HIV.....	204
Table 17.5.1	Accepting attitudes toward those living with HIV/AIDS: women	206
Table 17.5.2	Accepting attitudes toward those living with HIV/AIDS: men.....	207
Table 17.6	Attitudes toward negotiating safer sexual relations with husband.....	209
Table 17.7	Adult support of education about condom use to prevent AIDS.....	210
Table 17.8.1	Multiple sexual partners and higher-risk sexual intercourse in the past 12 months: women	212
Table 17.8.2	Multiple sexual partners and higher-risk sexual intercourse in the past 12 months: men	213
Table 17.9	Payment for sexual intercourse and condom use at last paid sexual intercourse: men.....	215
Table 17.10.1	Coverage of prior HIV testing: women	217
Table 17.10.2	Coverage of prior HIV testing: men	218
Table 17.11	Pregnant women counseled and tested for HIV.....	220
Table 17.12	Self-reported prevalence of sexually-transmitted infections (STIs) and STI symptoms	222

Table 17.13	Prevalence of medical injections	224
Table 17.14	Comprehensive knowledge about AIDS and of a source of condoms among youth	227
Table 17.15	Age at first sexual intercourse among youth.....	228
Table 17.16	Condom use at first sexual intercourse among youth.....	230
Table 17.17	Premarital sexual intercourse and condom use during premarital sexual intercourse among youth.....	232
Table 17.18.1	Higher-risk sexual intercourse among youth and condom use at last higher-risk intercourse in the past 12 months: women	233
Table 17.18.2	Higher-risk sexual intercourse among youth and condom use at last higher-risk intercourse in the past 12 months: men	234
Table 17.19	Drunkenness during sexual intercourse among youth.....	236
Table 17.20	Recent HIV tests among youth	237
Figure 17.1	Perceptions and beliefs about abstinence and faithfulness.....	199
Figure 17.2	women and men seeking treatment for STIs.....	223
Figure 17.3	Type of facility where last medical injection was received	225
Figure 17.4	Percentage whose last injection was given with a syringe and Needle taken from a new, unopened package	225
Figure 17.5	Abstinence, being faithful, and condom use (ABC) among young women and men	235

CHAPTER 18 HIV PREVALENCE AND ASSOCIATED FACTORS

Table 18.1.1	Coverage of HIV testing by residence and region: all respondents.....	242
Table 18.1.2	Coverage of HIV testing by sex, according to residence and region: women and men	243
Table 18.2	Coverage of HIV testing by selected background characteristics	244
Table 18.3.1	HIV prevalence by age: women	245
Table 18.3.2	HIV prevalence by age: men.....	245
Table 18.3.3	HIV prevalence by age: total women and men.....	246
Table 18.4.1	HIV prevalence by socioeconomic characteristics: women.....	247
Table 18.4.2	HIV prevalence by socioeconomic characteristics: men	248
Table 18.4.3	HIV prevalence by socioeconomic characteristics: women and men	249
Table 18.5	HIV prevalence by demographic characteristics	250
Table 18.6	HIV prevalence by sexual behavior	251
Table 18.7	HIV prevalence among young people by background characteristics.....	253
Table 18.8	HIV prevalence among young people by sexual behavior.....	254
Table 18.9	HIV prevalence by other characteristics.....	255
Table 18.10	Prior HIV testing by HIV status	255
Table 18.11	HIV prevalence among couples.....	256
Figure 18.1	HIV testing algorithm	240

CHAPTER 19 CHILDREN AT RISK

Table 19.1	Children's living arrangements and orphanhood	258
Table 19.2	School attendance by survivorship of parents	259
Table 19.3	Possession of basic material needs by orphanhood status	260

FOREWORD

We would like to introduce the Cambodia Demographic and Health Survey 2005 that is the second survey of this type conducted successfully in Cambodia. This survey is sponsored by USAID, ADB using a grant from DFID, UNFPA, UNICEF, and CDC/GAP. Technical assistance was provided by ORC Macro. The National Institute of Public Health (NIPH), Directorate General for Health, Ministry of Health, and the National Institute of Statistics (NIS) of the Ministry of Planning, were the project implementation agencies.

This main report includes information on demography, family planning, maternal mortality, infant and child mortality, domestic violence, women's status and health related information such as breastfeeding, antenatal care, children's immunization, childhood diseases, and HIV/AIDS. The questionnaires (household, man and woman questionnaires) are designed to evaluate the nutritional status of mothers and children and to measure the prevalence of HIV and anemia.

The 2005 CDHS findings are expected to be used by policymakers and program managers to evaluate the Cambodian demographic and health status in order to formulate appropriate population and health policies and programs in Cambodia. The programs of reproductive health and child health and health facilities need to be expanded and improved.

We would like to thank USAID, ADB, DFID, UNFPA, UNICEF, and CDC/GAP for sponsoring this survey project and ORC Macro for providing technical assistance. We gratefully acknowledge the support and encouragement extended by HE. San Sy Than, Director General, National Institute of Statistics, Dr. Ung Sam An, Director, National Institute of Public Health, Mr. Hor Darith, CDHS Survey Coordinator and Director of Census and Survey Department, NIS/MOP, Mr. Tith Vong, CDHS Survey Coordinator and Director, Social Statistics Department, NIS/MOP, Dr. Sao Sovanratnak, CDHS Survey Coordinator and Deputy Director, Planning and Health Information Department, MOH, Dr Saphonn Vonthanak, CDHS Survey Coordinator and Deputy Director, National Institute of Public Health, MOH, and other members of the 2005 CDHS Executive Committee and Technical Committee who contributed to the survey activities.

We express our sincere thanks to all persons involved in the survey implementation, analysis of the results and report writing for the 2005 CDHS and especially to NIS, NIPH, and Macro staff who contributed in making the survey a success.

Prof. Eng Huot
Secretary of State
for Minister of Health

Ouk Chay
Secretary of State
for Senior Minister
Minister of Planning

ACKNOWLEDGMENTS

The 2005 Cambodia Demographic and health Survey (CDHS 2005) represents the continuing commitment and efforts in Cambodia to obtain data on population and health. The survey also reflects the interest in obtaining information on maternal health, child health and anemia and HIV prevalence. The CDHS 2005 was sponsored by USAID, ADB using a grant from DFID, UNFPA, UNICEF, and CDC/GAP and it was implemented by the National Institute of Public Health (NIPH), Ministry of Health and the National Institute of Statistics (NIS) of the Ministry of Planning. This survey could not have been implemented without the active support and the efforts of many institutions and individuals. The active support and guidance of Excellencies Secretaries of State, HE. Prof. Eng Huot, Ministry of Health and HE. Ouk Chay, Ministry of Planning, are acknowledged with deep gratitude. We also gratefully acknowledge the representatives of USAID, DFID, UNFPA, UNICEF, and CDC/GAP and their staff for their support and valuable comments throughout the survey activities.

Our deep appreciation also goes to the ORC Macro team led by Mr. Bernard Barrère and his colleague Dr. Kia Reinis and others and they are acknowledged with gratitude for their support to facilitate and ensure the survey a success.

We would like to express our appreciation for all team leaders, field editors, and interviewers from NIS, NIPH, and central and local offices of Ministry of Planning and Ministry of Health whose dedicated efforts ensured the quality and timeliness of the survey and to all respondents for contributing their time and for giving the required information, enabling us to produce high-quality data for the country.

Finally, we would like to thank Dr. Saphonn Vonthanak, CDHS Survey Coordinator and Deputy Director of the National Institute of Public Health, MoH, Dr. Sao Sovanratnak, CDHS Survey Coordinator and Deputy Director, Planning and Health Information Department, Mr. Buth Sokhal, Head of NIPH Laboratory Bureau, Mr. Hor Darith, CDHS Survey Coordinator and Director of Census and Survey Department, NIS, and Mr. Tith Vong, CDHS Survey Coordinator and Director, Social Statistics Department, NIS.

Excellency San Sy Than
Director General
National Institute of Statistics

Dr. Ung Sam An
Director
National Institute of Public Health

SUMMARY OF FINDINGS

The 2005 Cambodia Demographic and Health Survey (CDHS) is a nationally representative sample of 16,823 women and 6,731 men age 15-49. The 2005 CDHS is the second comprehensive survey conducted in Cambodia as part of the worldwide Demographic and Health Surveys (DHS) projects. The primary purpose of the CDHS is to provide the policymakers and planners with updated and reliable data on fertility, family planning, infant, child and maternal mortality, maternal and child health, nutrition, malaria, knowledge of HIV/AIDS, prevalence of HIV, women's status and domestic violence. The 2005 CDHS is the first survey in Cambodia to provide population-based prevalence estimates for HIV.

FERTILITY

Survey results indicate that there has been a decline in the total fertility rate, from 4.0 births per woman in 2000 to 3.4 births per woman in 2005. Fertility continues to be lower in urban areas (2.8 births per woman) than rural areas (3.5 births per woman). There is a substantial differential in fertility by region ranging from a low of 2.5 births per woman in Phnom Penh to a high of 5.2 births per woman in Mondol Kiri/Rattanak Kiri. Both education and wealth have an effect on fertility. Women with secondary or higher education have 1.7 children less than women with no education and women living in the lowest wealth quintile have twice as many children as those living in the highest wealth quintile.

Women (age 25-49) begin having children at a median age of 22.0. Women living in urban areas have their first birth about one year later than women living in rural areas. Age at first birth is lowest in Mondol Kiri/Rattanak Kiri (20.7 years) and highest in Kampong Chhnang (23.3 years). Women with secondary and higher education begin childbearing at a slightly higher age than those with less education. Teenage childbearing is quite rare in Cambodia—only 8 percent of young women age 15-19 have begun childbearing.

Marriage and sexual initiation patterns are important determinants of fertility levels. Sixty percent of women interviewed are currently married. Women get married at a median age of 20.1. The median age at first marriage has been stable for the past 20 years. Women generally begin having sexual intercourse at about the same time as their first marriage, at the median age of 20.4. Women in urban areas wait about one year longer to get married and initiate sexual activity than those living in rural areas. Women with higher levels of education also tend to marry and initiate sex later than those with lower levels of education. Men marry at a median age of 22.1 and initiate sex slightly before marriage, at a median age of 21.5.

The interval between births is relatively long in Cambodia. The median number of months since the preceding birth is 36.8. Eighteen percent of nonfirst births occur within 24 months of a previous birth, while 30 percent occur 24 to 35 months after a previous birth. Thirty-one percent occur 36 to 59 months after a previous birth and 21 percent occur more than 60 months after a previous birth.

More than half (56 percent) of currently married Cambodian women do not want any more children. Another 23 percent would like to wait at least two years before their next child. On average, Cambodian women would like 3.3 children.

About 8 percent of women have ever had an induced abortion. Among those who have had an induced abortion, 44 percent have had more than one. Four percent of women have had an abortion in the past five years. These abortions most frequently took place at a private health facility or at someone's home. In almost 80 percent of cases, a doctor, nurse, midwife or other health worker assisted with the abortion.

FAMILY PLANNING

Almost all women are familiar with at least some methods of contraception. The daily contraceptive pill, the male condom, and

injectables are known by over 90 percent of married women. About half of women know at least one traditional method of family planning.

Almost two-thirds of currently married women have ever used a contraceptive method in their lifetime. Forty percent of married women are currently using a contraceptive method; 27 percent are using a modern method and 13 percent are using a traditional method. Use of contraception has increased substantially since 2000 when only 19 percent of married women were using a modern method. This is due primarily to the increase in use of the pill (from 5 percent to 11 percent).

Use of modern methods of contraception is higher in urban areas than rural areas (31 percent compared with 27 percent). Almost one-third of women with secondary or higher education use a modern method compared with 22 percent of those with no schooling. Use of modern methods is highest in Otdar Mean Chey (35 percent) and lowest in Mondol Kiri/Rattanak Kiri (19 percent).

Women access their contraception from a variety of sources. Pill and male condom users obtain their method from the public sector (primarily health centers) and other non-medical sources, such as shops and community distributors. Eighty-four percent of injectable users rely on the public sector (health centers) and the private medical sector.

Just over half of currently married women say that they intend to use family planning in the future. The daily pill and injectables are the two methods most favored for future use.

One-quarter of currently married women have an unmet need for family planning. That is, they do not want any more children or want to wait at least two years before their next birth but are not using a method of contraception. The unmet need for limiting (16 percent) is higher than the unmet need for spacing (9 percent). Unmet need is especially high among women in the lowest wealth quintile and women with no education. Currently 40 percent of the total need for family planning is being met.

CHILD HEALTH

The 2005 CDHS data show a remarkable decline in childhood mortality. Currently there are 66 infant deaths for every 1,000 live births and 83 under-five deaths for every 1,000 live births. In 2000, infant mortality was 95 and under-five mortality was 124. This represents a decrease of over 30 percent. Still, one in every 12 Cambodian children dies before reaching age 5. Four-fifths of these deaths occur in the first year of life.

Childhood mortality varies throughout Cambodia. It is much higher in rural areas (under-five mortality of 111) than in urban areas (under-five mortality of 76). Under-five mortality ranges from a high of 165 in Mondol Kiri/Rattanak Kiri to a low of 52 in Phnom Penh. Wealth and education are strongly linked with childhood death. Children whose mothers are in the lowest wealth quintile have a three times greater risk of death than those whose mothers are in the highest wealth quintile. Under-five mortality is also much higher for those whose mothers have received no schooling (136) than those whose mothers have attended secondary or higher levels of school (53).

Survival of infants and children is also strongly influenced by the sex of the child, mother's age at birth, birth order, and birth interval. Male children are more likely to die than female children. Childhood mortality is also highest among children whose mothers are over 40 years of age at birth. Childhood mortality increases with birth order— that is, first, second, and third children are at less risk of death than fourth, fifth, sixth or seventh children. Finally, children who are born less than 2 years after a sibling are at a much increased risk of infant and childhood death than those born 2 or more years after a sibling.

Two-thirds of children age 12-23 months have received all the basic recommended vaccinations (BCG, three doses of DPT and polio, and measles). In 2000, only 40 percent of children had received all of these vaccinations. Over 90 percent have received BCG, DPT 1, and polio 1, while fewer receive the second and third doses of DPT or polio and only 77 percent received the measles vaccine. Seven percent of children have received no vaccinations at all.

Vaccination coverage increases with household wealth and mother's education. Vaccination coverage is highest in Battambang/Krong Pailin (82 percent) and lowest in lowest in Mondol Kirk/Rattanak Kiri (35 percent).

Diagnosis and treatment of childhood diseases are essential to reducing mortality. Among children who had symptoms of acute respiratory infection in the 2 weeks before the survey, 48 percent were taken to a health facility or provider. Forty-three percent of children with fever received this same treatment. Only 37 percent of children with diarrhea were taken to a health provider. Thirty-six percent of children with diarrhea were treated with either oral rehydration therapy or recommended home fluids. Only 38 percent of children with diarrhea were given more fluids than usual during illness.

The 2005 CDHS collected information on ownership and use of mosquito nets. The data show that while almost all (96 percent) of households own a mosquito net, only 5 percent own an insecticide-treated net. The large majority (88 percent) of children under five slept under a mosquito net the night before the survey. Nine percent slept under an ever-treated net and 4 percent slept under an insecticide-treated net.

Thirty-five percent of children under five had a fever in the two weeks before the survey. Fever is a major manifestation of malaria, and children with fever should be treated for malaria. However, less than 1 percent of children with fever received an antimalarial drug.

MATERNAL HEALTH

Antenatal care from a health professional has almost doubled since 2000. Sixty-nine percent of women who had a live birth in the five years preceding the survey received antenatal care compared with only 38 percent in 2000. Antenatal care coverage is more common in urban areas (79 percent) than in rural areas (68 percent). Ninety percent of women with secondary and higher education receive antenatal care compared with only 50 percent of those with no education. Antenatal care coverage is highest in Svay Rieng (92 percent) and lowest in Mondol Kiri/Rattanak Kiri (28 percent). Forty-three percent of women have four or more antenatal care visits. Among those who received antenatal care,

only about one-third started antenatal care in the first three months of pregnancy.

Only 60 percent of those who received antenatal care reported that they were informed of the signs of pregnancy complications.

Just over two-thirds of women with a birth in the five years before the survey were protected from neonatal tetanus, either because they received two tetanus toxoid injections or because they had received injections during earlier pregnancies.

Only 22 percent of births in the five years before the survey took place in a health facility—78 percent took place at home. Still, this marks a great improvement since 2000 when only 10 percent of births occurred in a health facility. Health-facility births are far more common in urban areas (50 percent) than rural areas (17 percent) and among women with secondary or higher education and those in the highest wealth quintile. Forty-four percent of births were assisted by a trained health professional (doctor, nurse or midwife). This also represents a large improvement, as only about one-third of births received trained assistance in 2000. Seventy percent of births in urban areas receive assistance from a trained health provider, compared with only 39 percent in rural areas. Trained assistance at delivery is most common in Phnom Penh (86 percent of births) and least common in Preah Vihear/Steung Treng (13 percent).

The 2005 CDHS reports a maternal mortality rate of 472 deaths per 100,000 live births. This is comparable to the figure reported in 2000.

BREASTFEEDING AND NUTRITION

Almost all Cambodian children are breastfed. About one-third begin breastfeeding within an hour of birth, while two-thirds begin breastfeeding within a day of birth. Children are breastfed for an average of 21.6 months, but they are exclusively breastfed for only 4.1 months. Sixty percent of infants under six months are exclusively breastfed as recommended by WHO.

The CDHS includes biomarker testing for anemia as well as information on micronutrient intake. More than 60 percent of children age 6-59 months have some degree of anemia. The

anemia is moderate or severe in 33 percent of cases. The majority of children age 6-35 months had consumed foods rich in vitamin A and iron in the day before the survey. Thirty-five percent of children age 6-59 months had received vitamin A supplements in the 6 months before the survey. Only 2 percent had received iron supplements in the week before the survey. Almost three-quarters of households had adequately iodized salt.

The nutritional status of children has improved in the past 5 years. Currently 37 percent of children are stunted and 7 percent are wasted, compared with 45 and 15 percent in 2000. Stunting is most common in Pursat (62 percent) and least common in Phnom Penh (22 percent). In general, children with uneducated mothers and those living in the poorest households are most likely to be malnourished.

Women also suffer from nutritional deficiencies. Forty-seven percent of women have some degree of anemia. While most women consume foods rich in vitamin A, only 27 percent received a vitamin A dose post-partum. Only 18 percent took iron tablets or syrup for 90 or more days during pregnancy, as recommended.

Twenty percent of Cambodian women age 15-49 are considered thin, while 10 percent are overweight or obese. Underweight has remained stable over the last 5 years, while overweight has increased by 66 percent since 2000.

HIV/AIDS

Almost all Cambodians have heard of AIDS. More than 80 percent of women and men age 15-49 know the three major methods of preventing HIV transmission: using a condom, having only one faithful, uninfected partner, and abstaining. Misconceptions about HIV/AIDS are still fairly common. Only sixty-nine percent of women and 60 percent of men know that a healthy-looking person can have the AIDS virus and only about two-thirds know that AIDS cannot be transmitted by mosquito bites. Almost nine in ten women know that HIV can be transmitted to an infant through breastfeeding, but only 33 percent know that this risk can be minimized if the mother takes special drugs during pregnancy.

Certain behaviors put individuals at higher risk for contracting HIV. Less than 1 percent of women reported having higher-risk sex in the year before the survey, compared with 14 percent of men. Eighty-three percent of these men did report wearing a condom at last higher-risk sex. Six percent of men reported paying for sex in the year before the survey. Almost all of these men reported using a condom.

HIV testing is relatively uncommon in Cambodia. About half of men and women know where to get an HIV test, but only 10 percent of women and 14 percent of men have ever taken an HIV test and received the results.

Results from the 2005 CDHS indicate that 0.6 percent of Cambodian adults age 15-49 are infected with HIV. Prevalence is the same for women and men. HIV prevalence is three times higher in urban areas than in rural areas. HIV prevalence is three times higher among those living in the wealthiest households than those living in the poorest households. Men and women who are divorced, separated, or widowed have much higher infection rates than those who are currently married or have never been married. Men and women with 10 or more lifetime sexual partners are significantly more likely to have HIV than those with fewer partners. Interestingly, 40 percent of women and 44 percent of men who were HIV positive had been tested previously for HIV, while only 9 percent of HIV-negative women and 11 percent of HIV-negative men had ever taken an HIV test before.

Results show a higher infection rate among women who received antenatal care in a public health facility (0.8 percent) than those who did not receive any ANC in the past 3 years (0.5 percent). This helps to explain the difference seen between the national sentinel surveillance rate and the DHS population-based HIV rate.

The CDHS also examined children who are not living with both of their biological parents. Results show that 21 percent of children under age 18 are not living with both parents; however, in only 9 percent of cases have one or both of the parents died. Data indicate that orphans (those with one or both parents dead) are not significantly more lacking in basic needs (shoes, clothes, blankets) than non-orphans. Three-fourths of adult caregivers of children report that

they have made succession plans in case they should fall ill or die.

WOMEN'S STATUS AND DOMESTIC VIOLENCE

The 2005 CDHS includes modules on women's status and domestic violence. According to the data, 18 percent of women met their husbands for the first time on their wedding day. An additional 40 percent knew their husbands for less than one year before their wedding. In more than half of cases, the woman had no say in who she married. Most women have some decision-making power on issues such as visits to family and friends, daily household purchases and their own health care. Fewer than half have any say in decisions on whether or not she will work or whether to use contraception.

Many Cambodians have gender-biased attitudes. For example, only 53 percent of women disagree with the statement "important decisions should be made by men." Fifty-five percent of women agree that a husband has the right to beat his wife under certain circumstances. However, most women also agree that a wife has the right to refuse to have sex with her husband if she knows that he has a sexually transmitted infection or that he is having sex with other women.

While few women have sole ownership over land, their homes, or other valuables, most women share ownership of these items with someone else. However, only 24 percent can sell that asset without permission. About two-thirds of women control the money for at least one household item and one personal item.

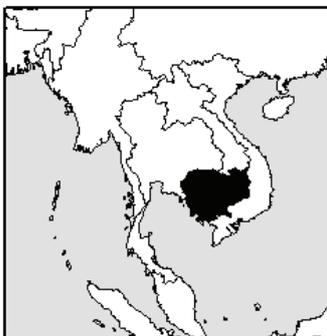

Twenty-two percent of ever-married women ever experienced violence since age 15. Ten percent of women have experienced violence in the year before the survey. In 44 percent of cases, the husband has been the sole perpetrator of the violence. Marital violence is not uncommon. Fourteen percent of ever-married women report that they have ever experienced physical or sexual violence by their husband. Nineteen percent report emotional violence. Six percent of women report that marital violence has resulted in bruises and aches; 1 percent reported that they have had an injury or broken bone as a consequence of marital violence. Marital violence is especially high among women whose husbands get drunk very often. It is also highest among husbands who exhibit a high degree of control over their wives.

Among all women who reported ever experiencing physical or sexual violence, 31 percent have ever sought help. In half of these cases, women seek help from their families.

USE OF HEALTH SERVICES FOR ACCIDENT OR INJURY

Two percent of household members were injured or killed in an accident in the year before the survey. Forty-six percent of injuries and deaths are attributed to road accidents. Sixteen percent of household members reported an illness or injury in the month before the survey. Among them, 92 percent sought a first treatment, 27 percent sought a second treatment and 10 percent sought a third treatment. The mean cost of these treatments ranged from US \$11.17 for the first treatment to US \$ 7.82 for the third treatment.

CAMBODIA

1.1 GEODEMOGRAPHY, HISTORY, AND ECONOMY

Geodemography

Cambodia is an agricultural country located in Southeast Asia. It is bounded by Thailand to the west, Laos and Thailand to the north, the gulf of Thailand to the southwest, and Vietnam to the east. It has a total land area of 181,035 square kilometers.

Cambodia has a tropical climate with two distinct monsoon seasons, which set the rhythm of rural life. From November to February, the cool, dry northeastern monsoon brings little rain, whereas the southwestern monsoon carries strong winds, high humidity, and heavy rains. The mean annual temperature for Phnom Penh, the capital city, is 27°C.

The 1962 census was the last official census to be conducted prior to 1998; it revealed a population of 5.7 million. The population census in 1998 recorded the number of the people in the country at 11,437,656 with an annual growth rate of 2.5 percent (National Institute of Statistics, 1999). The 2004 Inter-Censal Population Survey showed that the annual growth rate declined from 2.5 percent in 1998 to 1.81 percent in 2004, with the total population of 13.09 million (National Institute of Statistics, 2004). A large proportion of the population, 85 percent, live in rural areas, and only 15 percent live in urban areas. The population density in the country as a whole is 74 per square kilometer. More than a million inhabitants (1.044 millions) are living in Phnom Penh. The average size of the Cambodian household is 5.1. The total male to female sex ratio is 93.5. The literacy rate among adults age 15 and over is 73.6 percent. The male adult literacy rate (84.7 percent) is considerably higher than the rate of females (64.1 percent). Currently, it is estimated that approximately 34.7 percent of the total population lives below the poverty line.

History

Cambodia gained complete independence from France under the leadership of Prince Norodom Sihanouk on 9 November 1953. In March 1970, a military coup led by General Lon Nol overthrew Prince Sihanouk.

On 17 April 1975, the Khmer Rouge ousted the Lon Nol regime and took control of the country. Under the new regime, the country was renamed Democratic Kampuchea. Nearly three million Cambodian people died during the Khmer Rouge's radical and genocidal regime.

On 7 January 1979, the revolutionary army of the National Front for Solidarity and Liberation of Cambodia defeated the Khmer Rouge regime and proclaimed the country the People's Republic of Kampuchea and later in 1989 as the State of Cambodia.

The most important political event was the free elections held in May 1993 under the close supervision of the United Nations Transitional Authority in Cambodia (UNTAC). Since then, Cambodia was proclaimed the Kingdom of Cambodia and has a system of constitutional monarchy. Another two free and fair elections took place in 1998 and 2003. Now, Cambodia is stable and well on its way to democracy and a promising future.

Economy

Since the 1991 Paris Peace Accord, Cambodia's economy has made significant progress after more than two decades of political unrest. However, Cambodia still remains the poorest and least developed country in Asia, with the gross domestic product per capita estimated at approximately 1,400,000 Riel or \$339 in 2005 (US\$1= 4,128 Riel) (Ministry of Health, 2006). Agriculture, mainly rice production, is still the main economic activity for Cambodia. In addition, small-scale subsistence agriculture, such as fisheries, forestry, and livestock, are still the most important sector. In addition, garments factories and tourism services are also important components of foreign direct investment.

1.2 HEALTH STATUS AND POLICY

Health outcomes have been improved recently. The infant mortality rate has decreased from 95 per 1,000 live births in 2000 to 66 in 2005 and the under-five mortality rate from 124 to 83 in the same period. Life expectancy at birth is 58 for male and 64 for female (Ministry of Planning, 2006). The government expenditure on health per capita is \$4.09 (Ministry of Health, 2006). Despite progress made, the health status of the Cambodian people is still among the lowest in the region.

To improve the health status of the Cambodian people, the Ministry of Health developed the Health Sector Strategic Plan for 2003-2007 (Ministry of Health, 2002). Its policy statement follows:

- Implement sector-wide management through a common vision and effective partnerships among all stakeholders;
- Provision of basic health services to the people of Cambodia with the full involvement of the community;
- Provision of affordable, essential specialized hospital services;
- Decentralization and de-concentration of financial, planning and administrative functions within the health sector;
- Priority emphasis on prevention and control of communicable and selected chronic and non-communicable diseases, on injury, the elderly, adolescents and vulnerable groups such as the poor, and on managing public health crises;
- Priority emphasis on provision of good quality care to mother and child especially essential obstetric and pediatric care;
- Active promotion of healthy lifestyles and health-seeking behavior among the population;
- Emphasis on quality, effective and efficient provision of health services by all health providers;
- Optimization of human resources through appropriate planning, management including deployment and capacity development within the health system;
- Increase promotion of effective public and private partnerships for effective and efficient basic and specialist care;
- Effective use of the health information for evidence-based planning, implementation, monitoring and evaluation in the health sector;
- Implementation of health financing systems to promote equitable access to priority services especially by the poor; and
- Further development of appropriate health legislation to protect the health of providers and consumers.

1.3 OBJECTIVE AND SURVEY ORGANIZATION

The 2005 Cambodia Demographic and Health Survey (CDHS) is the second nationally representative survey conducted in Cambodia on population and health issues. It uses the same methodology as its predecessor, the 2000 Cambodia Demographic and Health Survey, allowing policymakers to use the two surveys to assess trends over time.

The primary objective of the CDHS is to provide the Ministry of Health, Ministry of Planning (MOP), and other relevant institutions and users with updated and reliable data on infant and child mortality, fertility preferences, family planning behavior, maternal mortality, utilization of maternal and child health services, health expenditures, women's status, domestic violence, and knowledge and behavior regarding HIV/AIDS and other sexually transmitted infections. This information contributes to policy decisions, planning, monitoring, and program evaluation for the development of Cambodia, at both national- and local-government levels.

The long-term objectives of the survey are to technically strengthen the capacity of the National Institute of Public Health (NIPH), Ministry of Health, and the National Institute of Statistics (NIS) of MOP for planning, conducting, and analyzing the results of further surveys.

The 2005 DHS survey was conducted by the National Institute of Public Health (NIPH), the Ministry of Health, and the National Institute of Statistics of the Ministry of Planning. The CDHS executive committee and technical committee were established to oversee all technical aspects of implementation. They consisted of representatives from the Ministry of Health, the National Institute of Public Health, Department of Planning and Health Information, the Ministry of Planning, the National Institute of Statistics, the U.S. Agency for International Development (USAID), Department for International Development (DFID), the United Nations Population Fund (UNFPA), and the United Nations Children's Fund (UNICEF). Funding for the survey came from USAID, the Asian Development Bank (ADB) (under the Health Sector Support Project HSSP, using a grant from the United Kingdom, DFID), UNFPA, UNICEF, and the Centers for Disease Control/Global AIDS Program (CDC/GAP). Technical assistance was provided by ORC Macro.

1.4 SAMPLE DESIGN

Creation of the 2005 CDHS sample was based on the objective of collecting a nationally representative sample of completed interviews with women and men between the ages of 15 and 49. To achieve a balance between the ability to provide estimates for all 24 provinces in the country and limiting the sample size, 19 sampling domains were defined, 14 of which correspond to individual provinces and 5 of which correspond to grouped provinces.

- Fourteen individual provinces: Banteay Mean Chey, Kampong Cham, Kampong Chhnang, Kampong Speu, Kampong Thom, Kandal, Kratie, Phnom Penh, Prey Veng, Pursat, Siem Reap, Svay Rieng, Takeo, and Otdar Mean Chey;
- Five groups of provinces: Battambang and Krong Pailin, Kampot and Krong Kep, Krong Preah Sihanouk and Kaoh Kong, Preah Vihear and Steung Treng, Mondol Kiri, and Rattanak Kiri.

The sample of households was allocated to the sampling domains in such a way that estimates of indicators can be produced with known precision for each of the 19 sampling domains, for all of Cambodia combined, and separately for urban and rural areas of the country.

The sampling frame used for 2005 CDHS is the complete list of all villages enumerated in the 1998 Cambodia General Population Census (GPC) plus 166 villages which were not enumerated during the 1998 GPC, provided by the National Institute of Statistics (NIS). It includes the entire country and consists of 13,505 villages. The GPC also created maps that delimited the boundaries of

every village. Of the total villages, 1,312 villages are designated as urban and 12,193 villages are designated as rural, with an average household size of 161 households per village.

The survey is based on a stratified sample selected in two stages. Stratification was achieved by separating every reporting domain into urban and rural areas. Thus the 19 domains were stratified into a total of 38 sampling strata. Samples were selected independently in every stratum, by a two stage selection. Implicit stratifications were achieved at each of the lower geographical or administrative levels by sorting the sampling frame according to the geographical/administrative order and by using a probability proportional to size selection at the first stage of selection.

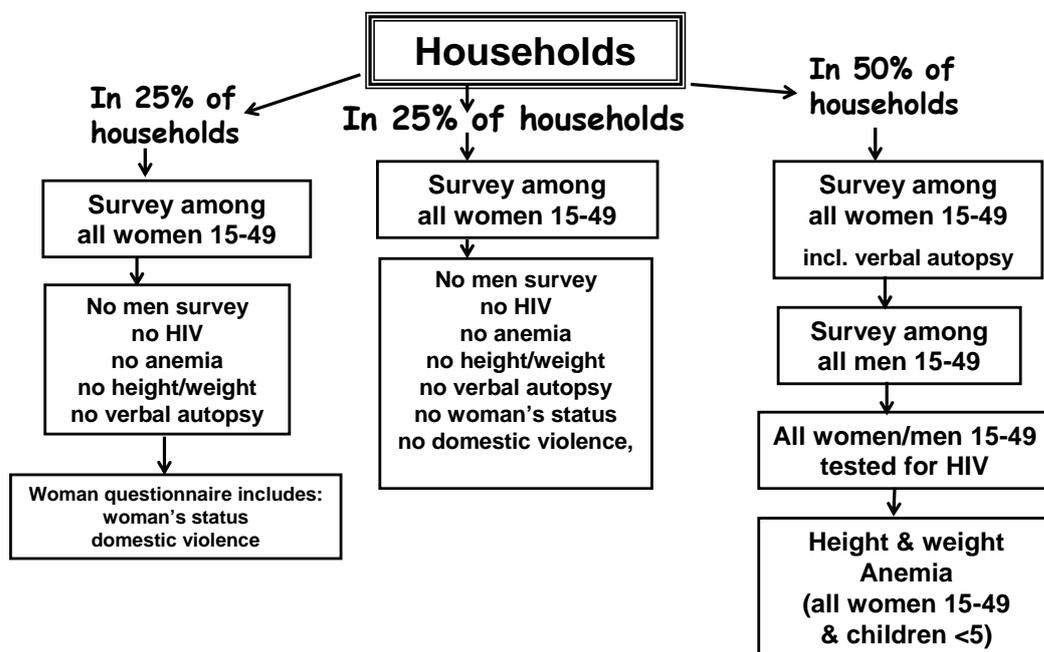

In the first stage, 557 villages were selected with probability proportional to village size. Village size is the number of households residing in the village. Some of the largest villages were further divided into enumeration areas (EA). Thus, the 557 CDHS clusters are either a village or an EA. A listing of all the households was carried out in each of the 557 selected villages during the months of February-April 2005. Listing teams also drew fresh maps delineating village boundaries and identifying all households. These maps and lists were used by field teams during data collection. The household listings provided the frame from which the selection of household was drawn in the second stage. To ensure a sample size large enough to calculate reliable estimates for all the desired study domains, it was necessary to control the total number of households drawn. This was done by selecting 24 households in every urban EA, and 28 households in every rural EA. The resulting over-sampling of small areas and urban areas is corrected by applying sampling weights to the data, which ensures the validity of the sample for all 38 strata (urban/rural, and 19 domains). Appendix A provides a complete description of the sample design and weighting procedures.

All women age 15-49 years who were either usual residents of the selected households or visitors present in the household on the night before the survey were eligible to be interviewed. In addition, in a subsample of every second household selected for the survey, all men age 15-49 were eligible to be interviewed (if they were either usual residents of the selected households or visitors present in the household on the night before the survey). The minimum sample size is larger for women than men because complex indicators (such as total fertility and infant and child mortality rates) require larger sample sizes to achieve sampling errors of reasonable size, and these data come from interviews with women.

In the 50 percent subsample, all men and women eligible for the individual interview were also eligible for HIV testing. In addition, in this subsample of households all women eligible for interview and all children under the age of five were eligible for anemia testing. These same women and children were also eligible for height and weight measurement to determine their nutritional status. Women in this same subsample were also eligible to be interviewed with the cause of death module, applicable to women with a child born since January 2002.

The 50 percent subsample not eligible for the man interview was further divided into half, resulting in one-quarter subsamples. In one-quarter subsample all women age 15-49 were eligible for the woman's status module in addition to the main interview. In this same one-quarter subsample, one woman per household was eligible for the domestic violence module. In the other one-quarter subsample, women were not eligible for the woman's status module, nor the domestic violence module. Figure 1.1 provides a diagram of the implementation of the survey modules.

**Figure 1.1 Implementation of Survey Instruments and Modules
2005 CDHS**

1.5 QUESTIONNAIRES

Three questionnaires were used: the Household Questionnaire, Woman Questionnaire, and Man Questionnaire. The content of these questionnaires was based on model questionnaires developed by the MEASURE DHS project. Technical meetings between experts and representatives of the Cambodian government and national and international organizations were held to discuss the content of the questionnaires. Inputs generated by these meetings were used to modify the model questionnaires to reflect the needs of users and relevant population, family planning, and health issues in Cambodia. Final questionnaires were translated from English to Khmer and a great deal of refinement to the translation was accomplished during the pretest of the questionnaires.

The Household Questionnaire served multiple purposes:

- It was used to list all of the usual members and visitors in the selected households and was the vehicle for identifying women and men who were eligible for the individual interview.
- It collected basic information on the characteristics of each person listed, including age, sex, education, and relationship to the head of the household.
- It collected information on characteristics of the household's dwelling unit, ownership of various durable goods, ownership and use of mosquito nets, and testing of salt for iodine content.
- It collected anthropometric (height and weight) measurements and hemoglobin levels.
- It was used to register people eligible for collection of samples for later HIV testing.
- It had a module on recent illness or death.

- It had a module on utilization of health services.

The Women's Questionnaire covered a wide variety of topics divided into 13 sections:

- Respondent Background
- Reproduction, including an abortion module
- Family Planning
- Pregnancy Postnatal Care and Children's Nutrition
- Immunization Health and Women's Nutrition
- Cause of Death of Children (also known as Verbal Autopsy)
- Marriage and Sexual Activity
- Fertility Preferences
- Husband's Background and Woman's Work
- HIV AIDS and Other Sexually Transmitted Infections
- Adult and Maternal Mortality
- Women's Status
- Household Relations (also known as Domestic Violence)

The Men's Questionnaire was administered to all men age 15-49 years living in every second household of the 2005 CDHS sample. The Man Questionnaire collected information similar to that of the Woman Questionnaire but was shorter as it did not contain as detailed a reproductive history, or questions on maternal and child health, or nutrition.

The CDHS underwent a full pretest in May 2005. Twenty four women and 23 men were trained in the administration of the CDHS survey instruments and blood collection techniques. Training and fieldwork included the Household Questionnaire, (not including anthropometry or testing of salt for iodine), the full 13 sections of the Woman Questionnaire, and the full Man Questionnaire. The training course was followed by five days of interviewing and blood collection, and a full day of interviewer debriefing. Constructive inputs of interviewers were used to refine survey instruments and logistics. Questionnaires were finalized as a result of pretest activities.

1.6 TRAINING AND FIELDWORK

The goal of training was to create 19 field teams capable of collecting data for the CDHS 2005. Each team was responsible for data collection in one of the 19 survey domains (comprised of the 24 provinces). Field teams were each composed of 6 people: team leader, field editor, three female interviewers, and one male interviewer. After three weeks of training on questionnaires, data entry staff had acquired the necessary knowledge of the survey instruments and were released from training. The 122 field personnel continued on for three more weeks of training: one week for blood training, one week on miscellaneous topics, and one week of field practice.

The first week of training was devoted to the Household Questionnaire. The next two weeks were devoted to 13 Sections of the Woman Questionnaire. Additional time was spent reviewing the Household Questionnaire, including the selection of women for the Household Relations Module, Consent Statements for blood collection, and conversion of ages and dates of birth between the Khmer and Gregorian calendar.

One week was devoted to additional activities: the Man Questionnaire, measuring height and weight of women and children, sample implementation and household selection (logistically complicated and required two days of training), collection of Geographic Positioning System data, testing of household salt for iodine, organization of documents and materials for return to the head office.

One week of main survey training was devoted to the collection of blood samples. All interviewers were designated to collect blood samples in the field, thus all interviewers were trained for blood collection procedures. While field editors and supervisors were not designated to collect blood samples in the field, they also underwent blood collection training so that all team members were fully aware of all responsibilities related to the collection of blood samples. Complete understanding of all survey activities by all team members contributed greatly to the maintenance of high data quality standards over a long period of data collection.

Training in the collection of blood samples included procedures for: identifying the correct household eligible for HIV testing in the 50 percent subsample; identifying men and women within those households eligible for HIV testing; obtaining voluntary consent of respondents; safety procedures in handling blood samples; techniques in capillary blood draw; use of the HemoCue machine for field testing of hemoglobin levels to assess levels of anemia; capturing blood samples for anemia testing; capturing blood samples for laboratory testing of HIV; providing referral for respondents needing treatment for anemia; providing vouchers for VCT services; providing HIV information pamphlets; rendering the blood sample for HIV anonymous; proper storage of dried blood spots in the field; packaging of dried blood spots for transport to the laboratory; disposal of bio-hazardous waste; and recording information in the questionnaires.

The five weeks of training were followed by a full week of field practice. Two supplementary days prior to launching fieldwork were required to cover fieldwork control forms, and supply teams with all necessary equipment. Each interviewer needs over 50 distinct items to perform a complete interview. Fieldwork was then launched, and teams disbursed to their assigned provinces.

During the training period, the 19 CDHS team leaders were provided with the cluster information for the provinces in which they would be working in order to devise a data collection sequence for their sample points. They were best equipped to perform this task as team leaders hailed from their own provinces. They also conducted the CDHS Household Listing operation (described in sample design) and therefore were well-acquainted with the areas in which they would have to work. The progression of fieldwork by geographic location had to take into account weather conditions during rainy season.

A fieldwork supervision plan was created for the six CDHS survey coordinators from NIS and NIPH and ORC Macro to conduct regular field supervision visits. Supervision visits were conducted throughout the six months of data collection and included the retrieval of questionnaires and blood samples from the field. In addition, a quality control program was run by the data processing team to detect key data collections errors for each team. Based on these data checks, regular feedback was given to each team based on their specific performance.

Data collection was conducted from 9 September 2005 to 7 March 2006.

1.7 DATA PROCESSING

Data entry on 19 personal computers began on 22 September 2005, just two weeks after the first interviews were being conducted. Data entry personnel attended questionnaire training of interviewers so as to become familiar with the survey instruments. Data processing personnel included a data processing chief, four assistants, 19 entry operators, and three office editors. Completed questionnaires were brought in from the field by survey coordinators and questionnaires and anonymous blood samples were logged by the office editors. Once proper accounting of

questionnaires and blood samples was accomplished on a per-cluster basis, blood samples were transported to the NIPH laboratory for later testing. Questionnaire data were entered at NIS using CSPro, a program developed jointly by the United States Census Bureau, the ORC Macro MEASURE DHS program, and Serpro S.A. All questionnaires were entered twice to minimize data entry error. Data entry was completed in April 2006. Internal consistency verification and secondary editing were completed in May 2005.

1.8 SAMPLE COVERAGE

All of the 557 clusters selected for the sample were surveyed in the 2005 CDHS. A total of 15,046 households were selected, of which 14,534 were identified and occupied at the time of the survey. Among these households, 14,243 completed the Household Questionnaire, yielding a response rate of 98 percent (Table 1.1).

In the 14,243 households surveyed, 17,256 women age 15-49 years were identified as being eligible for the individual interview. Interviews were completed with 16,823 of these women, yielding a response rate of 98 percent. Interviews with men were conducted in every second household. A total of 7,229 men age 15-49 years were identified in the subsample of households. Of these 7,229 men, 6,731 completed the individual interview, yielding a response rate of 93 percent.

Table 1.1 Results of the household and individual interviews			
Number of households, number of interviews, and response rates, according to residence, Cambodia 2005			
Result	Residence		Total
	Urban	Rural	
Household interviews			
Households selected	3,288	11,758	15,046
Households occupied	3,175	11,359	14,534
Households interviewed	3,101	11,142	14,243
Household response rate	97.7	98.1	98.0
Interviews with women			
Number of eligible women	4,278	12,978	17,256
Number of eligible women interviewed	4,152	12,671	16,823
Eligible woman response rate	97.1	97.6	97.5
Interviews with men			
Number of eligible men	1,728	5,501	7,229
Number of eligible men interviewed	1,586	5,145	6,731
Eligible man response rate	91.8	93.5	93.1

This chapter provides a summary of the socioeconomic characteristics of households and respondents surveyed, including age, sex, place of residence, educational status, household facilities, and household characteristics. The profile of the households provided in this chapter will help in understanding the results of the 2005 CDHS in the following chapters. In addition, it may provide useful input for social and economic development planning.

Throughout this report, numbers in the tables reflect weighted numbers. Due to the way the sample was designed, the number of weighted cases in some regions appears small, since they are weighted to make the regional distribution nationally representative. However, roughly the same number of households and women and men were interviewed in each province or group of provinces, and the number of unweighted cases is always large enough to calculate the presented estimates. Estimates based on an insufficient number of cases are shown in parentheses or not shown at all.

The 2005 CDHS survey collected information from all usual residents of a selected household (*de jure* population) and persons who had stayed in the selected household the night before the interview (*de facto* population). Although the difference between these two populations is small, to avoid double counting all tables in this report refer to the *de facto* population unless otherwise specified. The CDHS survey used the same definition of households as the 1998 census conducted by the National Institute of Statistics. A household was defined as a person or group of related and unrelated persons who live together in the same dwelling unit(s) or in connected premises, who acknowledge one adult member as head of the household, and who have common arrangements for cooking and eating meals.

2.1 CHARACTERISTICS OF THE HOUSEHOLD POPULATION

Age and Sex Composition

Age and sex are important demographic variables and are the primary basis of demographic classification in vital statistics, censuses, and surveys. They are also important variables in the study of mortality, fertility, and nuptiality. The effect of variations in sex composition from one population group to another should be taken into account in comparative studies of mortality. In general, a cross-classification with sex is useful for the effective analysis of all forms of data obtained in surveys.

The survey collected information on age in completed years for each household member. When the age was not known, interviewers inquired further for dates of birth in the Gregorian calendar, the Khmer calendar, and a historical calendar. The age was then calculated using conversion charts specifically designed for this purpose.

Table 2.1 presents the percent distribution of the household population by age, according to urban-rural residence and sex. The population spending the night before the survey in the households selected for the survey included 66,894 individuals, of which 47 percent were males and 53 percent were females.

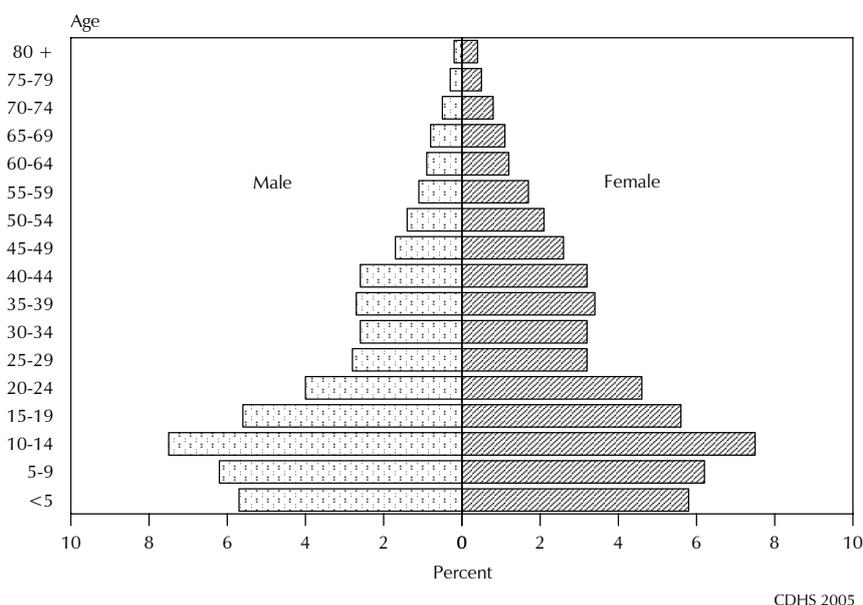

The age structure of the household population is typical of a society with a youthful population and recently declining fertility. The sex and age distribution of the population is also shown in the population pyramid in Figure 2.1. Cambodia has a broad-based pyramid structure due to half the population being under 20 years of age.

Table 2.1 Household population by age, sex, and residence

Percent distribution of the de facto household population by five-year age groups, according to sex and residence, Cambodia 2005

Age	Urban			Rural			Total		
	Male	Female	Total	Male	Female	Total	Male	Female	Total

Figure 2.1 Population Pyramid

Above the age of 10 years, the pyramid follows a usual pattern of decreasing numbers as age increases. However, those age 25 to 34 are fewer than would be expected as these are the two age groups born in the decade of the 1970s. The early 1970s saw escalating civil war and in the late 70s the Khmer Rouge ruled. This period of time was characterized by few births and high infant and child mortality.

Cambodia has a large dependent population of children and adolescents, although with declining fertility the proportion of the population under age 15 years has recently declined. Table 2.2 shows that children under 15 years of age account for 39 percent of the population. Fifty-seven percent of the population is in the age group 15-64, and nearly 5 percent are over 65 years of age.

Age	1998 Census ¹	2000 CDHS survey ²	2004 CIPS ³	2005 CDHS survey
< 15	42.8	42.7	38.6	38.9
15-49	46.9	46.3	49.5	47.9
50-64	6.8	7.4	8.0	8.6
65 +	3.5	3.6	3.9	4.6
Total	100.0	100.0	100.0	100.0

¹ General Population Census of Cambodia, 1998 (National Institute of Statistics, 1999)
² Cambodia Demographic and Health Survey, 2000 (National Institute of Statistics and ORC Macro, 2001)
³ Cambodia Inter-censal Population Survey, 2004 (National Institute of Statistics, 2004)

Household Composition

Table 2.3 shows the distribution of households in the survey by the sex of the head of the household and by the number of household members in urban and rural areas. Households in Cambodia are predominantly male-headed. However, one-quarter of households are headed by women, with 23 and 26 percent being female-headed households in rural and urban areas, respectively.

The average household size is 5.0 persons, smaller than the 5.4 persons per household observed in the 2000 CDHS. Rural households have 4.9 persons per household on average, and are slightly smaller than urban households (5.2 persons). Households with seven or more members are more common in urban areas (26 percent) than in rural areas (20 percent).

2.2 EDUCATION OF THE HOUSEHOLD POPULATION

Many behaviors, including those in the realm of reproduction, contraceptive use, child health, and proper hygiene, are affected by the education of household members. Information on the educational level of the male and female population age six and above is presented in Table 2.4. Survey results show that while the majority of Cambodians have not completed primary school, the country has experienced strong improvement in educational attainment over time. Overall, one in eight males has never attended school, while as many as one in four females has never attended school. Improvements over time have resulted in as few as 4 percent of girls and 5 percent of boys age 10-14 having never attended school at all.

Characteristic	Residence		Total
	Urban	Rural	
Household headship

Continued...

Half of the population has had some primary schooling without having completed primary school, male and female alike. However, 27 percent of the male population has gone on to attend secondary or higher schooling, while only 16 percent of females have had secondary or higher schooling. Improvements over time have resulted in approximately 40 percent of males in their twenties and thirties having gone on to secondary school, and approximately 25 percent of females in their twenties and thirties having done so. As would be expected, higher percentages of males and females in urban areas have gone on for secondary schooling than have rural males and females. There is a great deal of regional variation in educational attainment across provinces, with approximately 20-35 percent having never been to school. The outliers are Mondol Kiri/Rattanak Kiri and Phnom Penh, where 62 percent and 14 percent have never been to school, respectively. The percent of men who have never been to school clusters around 10 to 25 percent across provinces, with the same outliers of Mondol Kiri/Rattanak Kiri and Phnom Penh, where 44 percent and 5 percent have never been to school, respectively.

¹ Completed grade 6 at the primary level

² Completed grade 12 at the secondary level

School Attendance Ratios

Data on net attendance ratios (NARs) and gross attendance ratios (GARs) by school level, sex, residence, and province are shown in Table 2.5. The NAR indicates participation in primary schooling for the population age 6-12 and secondary schooling for the population age 13-18. The GAR measures participation at each level of schooling among those age 6-24. The GAR is nearly always higher than the NAR for the same level because the GAR included participation by those who may be older or younger than the official age range for that level. A NAR of 100 percent would indicate that all those in the official age range for the level are attending at that level. The GAR can exceed 100 percent if there is significant overage or underage participation at a given level of schooling. Overage for a given level of schooling occurs when students start school earlier, repeat one or more grades, or drop out of school and later return.

Table 2.5 School attendance ratios

Net attendance ratios (NAR) and gross attendance ratios (GAR) for the de facto household population by sex and level of schooling; and gender parity index (GPI), according to background characteristics, Cambodia 2005

¹ The NAR for primary school is the percentage of the primary-school age (6-12 years) population that is attending primary school. The NAR for secondary school is the percentage of the secondary-school age (13-18 years) population that is attending secondary school. By definition the NAR cannot exceed 100 percent.

² The GAR for primary school is the total number of primary school students, expressed as a percentage of the official primary-school-age population. The GAR for secondary school is the total number of secondary school students, expressed as a percentage of the official secondary-school-age population. If there are significant numbers of overage and underage students at a given level of schooling, the GAR can exceed 100 percent.

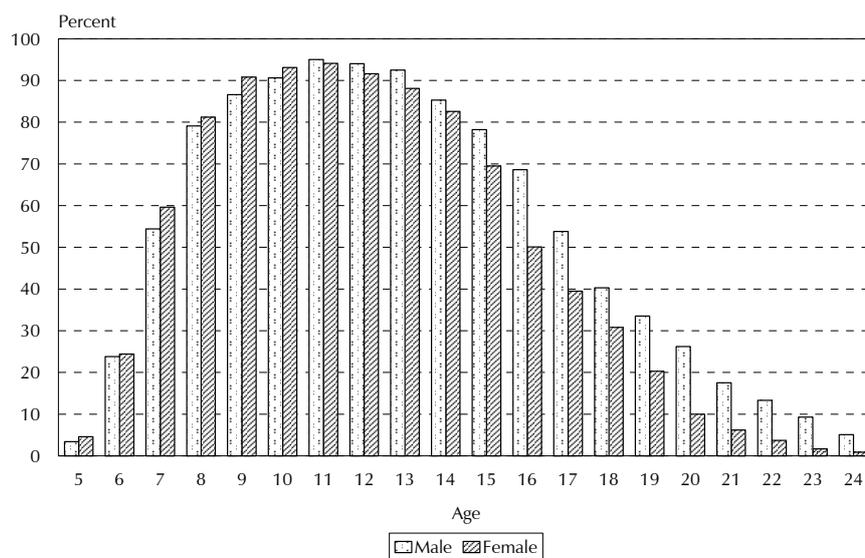

³ The gender parity index for primary school is the ratio of the primary school GAR for females to the GAR for males. The gender parity index for secondary school is the ratio of the secondary school GAR for females to the GAR for males.

Of those children who should be attending primary school, 77 percent are currently doing so. In 2000, 68 percent of children who should have been attending primary school were doing so. The NAR is significantly lower at the secondary school level, but has also improved since 2000. Twenty-eight percent of secondary-school-age youths are in school at that level, an increase from 16 percent in 2000. There is little difference between the NAR of males and females at both the primary and secondary level, as the NAR has increased since 2000 among females to equal that of males. The NAR among secondary-school-age females has increased since 2000 from 12 to 27 percent.

Table 2.5 also shows the Gender Parity Index (GPI) for primary and secondary school. The GPI for primary school is the ratio of the primary school GAR for females to the GAR for males. The GPI for secondary school is the ratio of the secondary school GAR for females to the GAR for males. The primary school GPI of 0.96 indicates near gender parity at the primary level, in both urban and rural areas. The GPI of 0.77 at the secondary school level reflects the fact that smaller proportions of girls attend secondary school than do boys, and the measure of gender parity varies across provinces far more greatly at the secondary school level than that at the primary school level.

Figure 2.2 illustrates age-specific attendance rates, the percentage of a given age cohort who attend school, regardless of the level attended (primary, secondary, or higher). Although the minimum age for schooling in Cambodia is six, there are some children enrolled prior to this age, and only one-quarter of children age six are attending school.

Figure 2.2 Age-specific Attendance Rates

Note: Figure shows percentage of the de jure household population age 5-24 years attending school.

CDHS 2005

Boys and girls attend school in about equal proportions up to and including age 14. Up to and including age ten, the proportion of girls attending school is slightly higher than for boys, and then slightly lower than for boys up to age 14. It is after age 14 that boys are attending school at a noticeably higher proportion than girls.

Grade Repetition and Dropout Rates

Repetition and dropout rates describe the flow of pupils through the system at the primary level. Repetition rates indicate the percentage of pupils who attended a particular grade during the school year that started in 2003, and who again attended that same class during the following school year beginning in 2004. The dropout rate shows the percentage of pupils in a grade during the school year that started in 2003 who no longer attended school the following school year that began in 2004. Table 2.6 shows repetition and dropout rates by primary school class, according to pupils' background characteristics.

¹ The repetition rate is the percentage of students in a given grade in the previous school year who are repeating that grade in the current school year.

² The dropout rate is the percentage of students in a given grade in the previous school year who are not attending school in the current school year.

Repetition rates for grade 1 are nearly the same for boys and girls, but boys have a slightly higher repetition rate in subsequent years of primary school. Repetition rates are slightly higher in rural areas than in urban areas. Overall, one-quarter of children repeat the first grade of primary school, and the repetition rate varies substantially across provinces.

There have been great strides in education in Cambodia and the low dropout rates attest to that fact. Once children enter primary school they are likely to finish. There are a few noticeable exceptions, however, such as in Mondol Kiri/Rattanak Kiri, where 14 percent of students dropped out after the fifth grade.

2.3 HOUSING CHARACTERISTICS

The type of water and sanitation facilities are important determinants of the health status of household members and particularly of children. Proper hygienic and sanitation practices can reduce exposure to and the seriousness of major childhood diseases such as diarrhea. The CDHS asked respondents about the household source of drinking water, the time required to get to the source of that water, and the type of sanitation facility used by the household. In Cambodia, the source of drinking water can vary between the dry season and the rainy season, so separate questions were asked for the different seasons. If households had more than one source of drinking water, respondents were asked to identify the most commonly used source.

Water Supply

Table 2.7 shows that sources of drinking water were the same during the dry and rainy seasons for three-quarters of urban households and over 60 percent of rural households. The source of drinking water is an indicator of whether it is suitable for drinking. Sources which are considered likely to be of suitable quality are listed under “Improved source,” and those which may not be of suitable quality are listed under “Non-improved source.” The categorization into improved and non-improved is proposed by WHO, UNICEF, and the Joint Monitoring Programme (JMP) for Water Supply and Sanitation.

During the dry season, 43 percent of households in Cambodia consume drinking water from a non-improved source. This percent declines to 24 percent of households during the rainy season, as more households utilize rainwater for drinking water. The main source of drinking water during the rainy season is rainwater for one-third of households. Rainwater is the most common source of drinking water during the rainy season for rural households and for urban households that do not have water piped into their dwelling or property. Much of the increase in use of non-improved water sources during the dry season is due to a increased reliance on surface water.

Even if water is not piped directly into the dwelling or yard, it is common for the source of water to be on the household premises, especially during the rainy season. Two-thirds of rural households and 80 percent of urban households report that their source of drinking water during the rainy season is located on the household premises. During the dry season, the percentage of households with their source of drinking water on the premises declines to 63 percent and 38 percent among urban and rural households, respectively. For those households not having a source of drinking water on the premises nor having water delivered, the majority are within a 30 minute or less roundtrip time of obtaining it. During the dry season only about 10 percent have 30 minutes or longer away from a source (or don't know), compared with the rainy season, where that number drops to just over three percent requiring 30 minutes or more (or not knowing the time required). The person to most commonly retrieve the water is an adult, either male or female in generally equal proportion.

Table 2.7 Household drinking water

Percent distribution of households by source of drinking water, time to collect water (if not within residence or plot), person fetching the water, and percentage of households using various modes for treating drinking water, according to residence; and percent distribution of the de jure population by household drinking water arrangements and percentage of the de jure population living in households using various modes to treat drinking water, Cambodia 2005

Continued...

Nearly 60 percent of rural households boil their water prior to drinking, and three-quarters of urban households do so. Among those who do not boil their water, the most common action is to do nothing to treat the water prior to drinking. One-third of rural (36 percent) and one-fifth of urban households (20 percent) report they do nothing to treat their drinking water prior to consuming it. Overall, one-third of households do nothing to treat their water prior to drinking. Twelve percent of households allow the water to stand and settle prior to drinking.

Table 2.7—Continued

¹ Because the quality of drinking water is not known, households using bottled water for drinking are classified as using an improved or non-improved source according to their water source for cooking and washing.

² Respondents may report multiple treatment methods so the sum of treatment may exceed 100 percent.

Sanitation Facilities

A household's toilet facility is classified as hygienic if it is used only by households members (is not shared by other households) and if the type of toilet effectively separates human waste from human contact. The types of facilities most likely to accomplish this are flush or pour flush into a piped sewer system/septic tank/pit latrine, ventilated, improved pit (VIP) latrine, pit latrine with a slab and a composting toilet. A household's sanitation facility is classified as unhygienic if it is shared with other households or if it does not effectively separate human waste from human contact. Categories are those proposed by WHO, UNICEF, and JMP.

Table 2.8 Household sanitation facilities

Percent distribution of households by type of toilet/latrine facilities, according to residence, and the percent distribution of the de jure population by type of toilet facilities, Cambodia 2005

Type of toilet/ latrine facility	Residence		Total	De jure population
	Urban	Rural		
Improved, not shared				
Flush/pour flush to piped sewer system	28.9	1.1	5.2	5.7

Not improved				
Any facility shared with other households	7.1	4.1	4.5	4.3
Flush/pour flush not to sewer/septic tank/pit latrine	0.9	0.1	0.2	0.2
Pit latrine without slab/open pit	0.7	0.9	0.9	0.9
Bucket	0.2	0.1	0.1	0.1
Hanging toilet/hanging latrine	2.0	0.7	0.9	0.8
No facility/bush/field	32.3	78.1	71.4	70.1
Other	0.6	0.2	0.2	0.2
Total	100.0	100.0	100.0	100.0
Number	2,066	12,177	14,243	70,637

Households vary greatly in access to hygienic facilities by urban and rural residence, as shown in Table 2.8. The majority of households in rural areas have no toilet facility, with three out of four households reporting no toilet facility and making use of fields or bush areas. In urban areas, one in three households has no toilet facility; however, one-half of urban households does use a flush or pour toilet that is piped to a sewer or septic system.

Table 2.9 presents the distribution of households by the characteristics of the dwelling in which they live. In urban areas, two out of three households live in dwellings with electricity, while in rural areas, only one in every five households has electricity. Wood planks provide the most common type of flooring material in both urban and rural areas. Four out of ten urban households live in dwellings with wood planks, followed by one-quarter who live in dwellings with ceramic tiles. In rural areas, one-half of households live in dwellings with wood plank flooring, followed by one-third who live in dwellings with palm or bamboo flooring. If there was more than one type of flooring, interviewers recorded the predominant flooring material. Most households sleep together in one room, although in urban areas, 30 percent of households use two or more rooms for sleeping.

Cooking Arrangements

Nine in ten rural households use firewood or straw for cooking fuel. While firewood or straw is also the most common source of fuel for cooking in urban areas, there is more variability in urban areas as to what is used for cooking fuel. Forty-four percent of urban households use firewood or straw, 30 percent use liquid petroleum or natural gas, and 25 percent use charcoal. Nearly all households do their cooking over an open fire, without a chimney to divert the smoke. One-half of urban households and one-third of rural households report that they do their cooking in the house.

2.4 HOUSEHOLD POSSESSIONS

Information on ownership of durable goods and other possessions is presented in Table 2.10. The availability of durable consumer goods is a good indicator of household socioeconomic level, and particular goods have specific benefits. For example, radio access can increase exposure to innovative ideas, whereas transport vehicles can provide access to services out of the local area.

Over one-half of all households in Cambodia own a television, an increase from one-third of all households in 2000. One in five households owns a mobile telephone, up from four percent in 2000. Ownership of mobile telephones is far more common among urban households (55 percent), but not unknown in rural households (14 percent). Ownership of transportation has increased since 2000 as well. Fifteen percent of urban households now own a car or truck, having increased from 10 percent in 2000. One-third of all households own a motorcycle, an increase from one-quarter of households in 2000. Percentage of households owning a boat remains unchanged, at nine percent.

The 2005 CDHS found that nearly three-quarters of all households own some land, and that three-quarters of all households own at least one farm animal.

2.5 HOUSEHOLD WEALTH

In addition to standard background characteristics, many of the results in this report are shown by wealth quintiles, an indicator of the economic status of households. The CDHS did not collect data on consumption or income, but the information collected on dwelling and household characteristics, consumer goods, and assets are used as a measure of socio-economic status. The resulting wealth index is an indicator of the level of wealth that is consistent with expenditure and income measures.

Each household asset for which information is collected is assigned a weight or factor score generated through principal components analysis. The resulting asset scores are standardized in relation to a standard normal distribution with a mean of zero and a standard deviation of one.

These standardized scores are then used to create the break points that define wealth quintiles. Each household is assigned a standardized score for each asset, where the score differs depending on whether or not the household owned that asset (or, in the case of sleeping arrangements, the number of people per room). These scores are summed by household, and individuals are ranked according to the total score of the household in which they reside. The sample is then divided into population quintiles, i.e., five groups with the same number of individuals in each. At the national level, approximately 20 percent of the household population is in each wealth quintile.

A single asset index is developed on the basis of data from the entire country sample and used in all the tabulations presented. The reader should keep in mind that wealth quintiles are expressed in terms of quintiles of individuals in the population, rather than quintiles of individuals at risk for any one health or population indicator. For example, the quintile rates for infant mortality refer to the infant mortality rates per 1,000 live births among all people in the population quintile concerned, as distinct from quintiles of live births or newly-born infants, who constitute the only members of the population at risk of mortality during infancy.

The wealth index has been compared against both poverty rates and gross domestic product per capita for India, and against expenditure data from household surveys in Nepal, Pakistan, and Indonesia (Filmer and Pritchett, 1998) and Guatemala (Rutstein 1999). The evidence from those studies suggests that the assets index is highly comparable to conventionally-measured consumption expenditures.

Table 2.11 shows the distribution of the *de jure* household population into five wealth quintiles (five equally divided levels) based on the wealth index by residence. These distributions indicate the degree to which wealth is evenly (or unevenly) distributed across Cambodia. As expected, urban areas are wealthier than rural areas. For example, 87 percent of Phnom Penh's population falls in the highest wealth quintile. By contrast, the province with the lowest representation in the highest wealth quintile is Otdar Mean Chey, with only five percent of its population in the highest wealth quintile.

Table 2.11 Wealth quintiles

2.6 BIRTH REGISTRATION

The registration of births is the inscription of the facts of the birth into an official log. A birth certificate is issued as proof of the registration of the birth. Information on the registration of births was collected in the household interview by asking whether children under five years of age had a birth certificate. If the interviewer was told that the child did not have a birth certificate, the interviewer probed further to ascertain whether the child's birth had been registered with the civil authority. One-half of children have a birth certificate and a total of two-thirds of children under age five are registered, although levels of registration vary greatly across the country, as shown in Table 2.12.

Table 2.12 Birth registration of children under age five

Percentage of de jure children under five years of age whose births are registered with the civil authorities, according to background characteristics, Cambodia 2005

Background characteristic	Percentage of children whose births are registered			Number of children
	Had a birth certificate	Did not have a birth certificate	Total registered

When the NHS 1998 was undertaken, the Ministry of Health was beginning to implement a redesigned Health Coverage Plan created to improve the accessibility and quality of government health services. The major points of the new health care plan were to create a network of health centers throughout the country delivering the “Minimum Package of Activities” services. The data collected in the 1998 NHS was considered to be a baseline of health conditions in the country before implementation of the new health coverage plan. The 2000 CDHS data were used to provide a first-round analysis of health care delivery under the new plan; the 2005 CDHS provides an update to those findings.

Utilization of health services was assessed in the household questionnaire. The questions were asked to all households in the sample. First, information was collected to assess the prevalence of injuries and deaths due to accidents in the past year. Second, the respondent was asked if any household members suffered from any physical impairment. Third, the respondent was asked about the severity of illness or injury and the subsequent utilization of health services for all members of the household who had been ill or injured in the 30 days prior to the interview.

3.1 ACCIDENTAL DEATH OR INJURY

All households reported on whether any household member had suffered accidental injury or death in the past 12 months preceding the day of the household interview. If anyone had been injured, the cause of the injury was recorded. The respondent to the household questionnaire was further asked whether the accident victim was alive or dead, and if dead, whether the death was the result of the reported accident. The questions were designed in this order to definitively assess the cause of injury, and the cause of death, if a death was noted.

Frequency of Accidental Death or Injury

Accidental injuries and deaths in Cambodia were not common (Table 3.1). Two percent of the population had suffered an injury or death by accident in the past 12 months. Accidental injuries were much more common than accidental deaths; for every 1,000 people in the population, 18 suffered an injury and for every 1,000 people in the population, one person suffered an accidental death.

The percentage of the population injured in the past 12 months increases with age from 1.1 percent among children aged 0-9 years to a peak of 2.4 percent among adults aged 20-39 years. The percentage experiencing accidental injury decreases thereafter, to 2 percent among adults age 40 and above. The occurrence of accidental death does not vary by age. For all ages, only 0.1 percent or one out of one thousand persons died as the result of an accident.

Males were more than twice as likely as women to be injured in an accident. Overall, 2.7 percent of men were injured in an accident in the past 12 months, compared with 1.1 percent of women. Despite the differences of accidental injuries by sex, men and women perished in accidents at the same rate (0.1 percent). While there were no substantial differences in accidental injuries by urban/rural residence, there are differences across provinces. The highest percentage of accidental injury was reported in Kampong Thom, with 4.4 percent of the household population experiencing an injury in the previous 12 months. The lowest percentage of accidental injury was in Otdar Mean Chey and Krong Preah Sihanouk/Kaoh Kong (both 0.7 percent). While Otdar Mean Chey has a low percentage of injuries, it has the highest percentage of accidental deaths (0.7 percent); otherwise, the percentage of accidental death ranges between 0.1 and 0.2 percent across provinces.

Type of Accident

Originally the question about the type of accident was created to assess the impact of landmines on the population. However, due to the large increase in the use of motorized vehicles in Cambodia, data on prevalence of road accidents was also included in the CDHS. Table 3.2 shows that road accidents account for the greatest proportion of accidental injuries and deaths. Forty-six percent of those who had been injured or killed in the previous 12 months were as a result of a road accident. Fourteen percent of injuries/deaths were the result of a fall, and 4 percent were the result of an animal bite. Four percent of injuries/deaths were the result of some form of violence, and an additional 1 percent from gun shot. Fatalities due to landmines are decreasing in relevance as a threat to safety, dropping from 3 percent of cases in the 2000 CDHS to the current level of 0.7 percent of all injuries/deaths. Twenty-six percent of injuries/deaths were from unknown causes.

Table 3.2 Injury and death in an accident by type of accident

Percent distribution of the de facto household population who were injured or killed in an accident in the past 12 months by type of accident, according to background characteristics, Cambodia 2005

Total	0.7	1.4	45.9	1.7	4.4	14.2	0.7	0.6	3.8	26.1	0.5	100.0	1,298

Note: Total includes 16 people for whom information on age is not available. Figures in parentheses are based on 25-49 unweighted cases. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.

Cause of injury/death varies by age, but road accidents are the most commonly cited source of injury/death for people of all ages, especially for those age 20-59. Animal bites account for ten percent of injuries among children aged 0-9, declining as a cause of injury as the population ages. Gunshots and landmines account for a higher percentage of injuries/deaths (5 and 4 percent, respectively) among people age 60 and above than for any other age group. Unspecified violence accounts for a greater percentage of injury/death (6 percent) among people age 20-39 as compared with people of other ages.

There were other significant differences in accidental injuries and deaths in the last 12 months by sex, urban/rural residence, and province. Men were more likely than women to be injured or killed in a road accident (48 percent versus 41 percent), as a result of unspecified violence (5 percent versus 2 percent), or by gunshot (2 percent versus less than 1 percent). Not surprisingly, road accidents account for a higher percentage of injuries/deaths in urban areas (65 percent) than in the rural areas (43 percent). Falls account for a higher proportion of accidents in rural areas than in urban areas (15 percent versus 7 percent). The distribution of causes of injuries/deaths by province should be analyzed with caution due to small sample sizes in selected provinces.

Table 3.3 Physical impairment

Percentage of the de facto household population physically impaired and percent distribution of the impaired de facto household population by cause of impairment, according background characteristics, Cambodia 2005

Note: Figures in parentheses are based on 25-49 unweighted cases.

3.2 PHYSICAL IMPAIRMENT

Questions on physical impairment include inquiring if any living household members were physically impaired, and if so what was the cause. In Cambodia, 2 percent of the population has a physical impairment (Table 3.3). Physical impairments increases with age. Persons aged 60 years and older are more likely than younger persons to have physical impairments (5 percent compared with 4 percent or less). Males are more likely (3 percent) to be impaired physically than women (1.5 percent). There are minor differences in physical impairments by urban/rural residence (1.8 and 2.2 percent respectively), although there are differences by province. The province with the highest percent of the population with physical impairments was Kampong Chhnang (4 percent). The provinces with the lowest prevalence of physical impairments (1.2-1.3 percent) were Kampong Cham, Kratie, Kampot/Krong Kep, and Mondol Kiri/Rattanak Kiri.

Table 3.3 also shows the cause of physical impairments in Cambodia. The most common cause of impairment were illness (33 percent). Other causes of impairments were due to unspecified accidents (22 percent) and birth defects (19 percent).

The causes of impairments are presented by age, sex, residence, and province. The cause of impairment varied significantly by age. Impairments at birth were most likely to be reported for children age 0-9 years (48 percent). On the other hand, other causes of impairment increased with age. For example, the percentage of the population impaired due to illness increases from 21 percent for age 0-9 to 60 percent for age 60 and older. Landmines and gunshots mostly affected persons age 40-59. Impairments caused by road accidents and other accidents varies less by age than by other causes of impairment.

The cause of impairment varies by sex, residence, and province. Men were much more likely than women to have been impaired by landmines and gunshot accidents. While 15 percent of men were impaired by a landmine, only 2 percent of women suffered a similar fate. Twelve percent of men were impaired by a gunshot compared with 2 percent of women. There were less striking differences by rural/urban residence in causes of impairments. As in Table 3.2, the interpretation of the causes of physical impairment by province in Table 3.3 is complicated by the small number of cases in some provinces.

3.3 PREVALENCE AND SEVERITY OF ILLNESS OR INJURY

All households were asked if any members were sick or injured at any time in the 30 days before the interview. If any members were sick, their names were recorded to ask specifically about their conditions in the questions that followed. The household questionnaire allotted space for information to be recorded for up to three household members. Interviewers were instructed to use extra questionnaires to record the information on all household members who were ill or injured. The respondent was asked to judge the illness or injury as slight, moderate, or severe. Finally questions were asked as to whether the ill or injured household member sought care, where they sought care, how much they spent on transport, and how much they spent on treatment. These questions were repeated in order to collect information on the patterns of health-care-seeking behavior. For example, a man might first seek treatment from a Kru Khmer traditional healer, but later go to a health clinic if the illness continues. Up to three health-seeking attempts were recorded in the questionnaire for each ill or injured person.

Sixteen percent of household members were ill in the 30 days prior to the interview (Table 3.4). However, this percentage may under-represent the actual prevalence of morbidity and injury for two reasons. The questions were asked only about living household members at the time of the interview. Therefore, the recorded episodes of illness and injury exclude any cases that ended in the death of a household member in the 30 days prior to the interview. Furthermore, the responses are based on the 30 day recall of one respondent in the household. That respondent might not have been aware of all the illnesses or injuries that had occurred within the household. It is likely that illnesses or injuries that occurred at the beginning of the 30 day period or those that were of mild severity were forgotten and not reported.

Nine-tenths of all illnesses or injuries were slight or moderate in severity. Only 2 percent of the household members experienced serious illness or injury, with those 40 years and older suffering from the most illnesses and injuries. The highest percentage of illness or injury was found among persons age 60 years and older; 10 percent had slight illness or injury, 15 percent had moderate illness or injury, and 5 percent reported serious illness or injury. There were only slight differences by sex and rural/urban residence. The highest percentage of illness or injury was found in Battambang/Krong Pailin (33 percent). The province with the lowest percent of illness or injury is Krong Preah Sihanouk/Kaoh Kong (4 percent).

Table 3.4 Prevalence and severity of illness or injury in previous 30 days

3.4 TREATMENT SOUGHT FOR ILLNESS OR INJURY

Table 3.5 presents the percentage of the ill or injured population who sought treatment according to the number of times. The type of treatment recorded in these questions include, but was not limited to, care given by medically-trained professionals. For example, if a sick child was first given a remedy by a Kru Khmer traditional healer, this was recorded as the first treatment. If the parents later observed that the child was still ill and went to a shop in the market for medicine, this was recorded as the second treatment. If the drugs did not work and the parents took the child to a doctor at a private clinic, this was recorded as the third treatment.

Ninety-two percent of household members who were ill sought at least one treatment (Table 3.5). This continues the upward trend found in the NHS 1998 (86 percent) and the 2000 CDHS (89 percent). Twenty-seven percent of those ill or injured sought at least two treatments, and 10 percent sought at least three treatments. In general, there was a positive relationship between the severity of illness or injury and the number of times treatment is sought. Those persons with serious illnesses or injuries were more likely to seek treatment than those with moderate illnesses or injuries. These latter individuals were in turn were more likely to seek treatment than those with slight illnesses or injuries. For first time treatments, the percent seeking treatment was fairly similar (88, 94, and

96 percent respectively for slight, moderate, and serious illness or injuries) than for second treatment (23, 27, and 40 percent respectively). For instance, 10 percent of slight illness or injury were treated three times or more compared with 16 percent of those with a serious illness or injury. There were small differences in health-seeking behavior by sex, age, and urban/rural residence.

The province with the highest percentage of ill or injured persons seeking treatment is Battambang/Krong Pailin (98 percent), while the province with the lowest percentage is Mondol Kiri/Rattanak Kiri (76 percent).

Note: Total includes 12 people for whom information on severity of illness is not available.

3.5 UTILIZATION OF HEALTH CARE FACILITIES

Information on the sector and location of health care providers was collected to determine where persons who were ill or injured went for treatment. The health care providers were distinguished by public sector, private sector, and non-medical sector. Descriptions of the different types of hospitals, clinics, pharmacies, and other health venues were explained to the interviewers. During data collection if the interviewer had difficulties distinguishing among the various types, then the team supervisor or field editor would ascertain the correct designation from local sources.

Table 3.6 presents the utilization of health services by type of residence (urban/rural), where small differences in the pattern of health care use can be observed. In general, the private sector was consistently the most popular, with the public sector as commonly used as the non-medical sector. Urban and rural residents seek a first, second, or third treatment in about equal proportion. Approximately nine in ten ill or injured people sought treatment, one in four went on for a second treatment, and one in ten went on for a third treatment.

Table 3.6 Percentage of ill or injured population who sought treatment

PP = Phnom Penh
RH = Referral hospital

Within the public sector, health centers were most often used in both urban and rural areas. In fact, health centers in rural areas were twice as likely to be visited for first treatment than health centers in urban areas (14 percent compared with 8 percent). Within the private sector, private pharmacies were much more likely to be visited for first treatment in urban areas than in rural areas (25 percent compared with 7 percent), whereas trained health workers and nurses were more commonly sought out for first time treatment in rural areas than in urban areas (19 percent versus 11 percent). Within the nonmedical sector, the overwhelming choice for source of health care were shops or markets.

Figure 3.1 summarizes the findings in Table 3.6. The private sector is about twice as likely to be visited for all treatments. Public sector is as popular as the non-medical sector for first, second and third treatments.

Figure 3.1 Percentage of Household Members Ill or Injured Seeking Treatment by Order of Treatment and Sector of Health Care

3.6 COST FOR HEALTH CARE

Distribution of Cost for Health Care

For each ill or injured person, the respondent was asked to state the costs expended for transportation and treatment for each visit to a health care provider. These costs are reported only for living people who have been recently ill or injured, and does not include costs incurred for people who died in the 30 days prior to interview. Costs are presented in US dollars in Table 3.7. For all treatments, 22 percent of household members spent US \$1.00 or less and 33 percent spent \$1.00 to \$4.00. Just under 4 percent of all household members spent \$50-\$99.00 for the transport to and treatment of illness or injury, while only 2.5 percent of all ill or injured persons spent \$100.00 or more for transport to and treatment of illness or injury.

These expenditures vary by the type of spending. For transport, two out of three household members spent less than \$1.00, 21 percent spent \$1.00 to \$4.00, and barely 6 percent spent \$5.00 or more for transport. For health care, 56 percent spent up to \$4.00, 15 percent spent between \$5.00 and \$9.00, and 11 percent spent between \$10.00 and \$19.00.

There are small variations according to the order of treatment. For the first through third treatments, 69 to 76 percent of all ill or injured persons spent less than \$1.00 for transport. For health care, these proportions are less varied, between 29 and 32 percent.

Expenditures for Health Care

Table 3.8 presents the mean cost of transport and treatment by the order of treatment and background characteristics. There is an inverse relationship between the cost and the order of treatment. As the number of treatments rise, the total cost for treatment decreases from \$11.17 for the first treatment to \$7.82 for the third treatment. The mean cost of transport does not follow a specific pattern; for all order of treatments the cost for transport is less than one dollar.

The mean cost of transport and health care varies according to the type of health sector, severity of illness or injury, age group, sex, residence, and province. Examining transport costs by type of health sector shows that the highest mean expenditure is for “other” type of treatment; this may include going to another country such as Thailand or Vietnam, or going to trained medical professionals with specialized services. Examining health care costs by type of health sector shows that the highest mean expenditure is for the private sector, with costs barely diminishing over treatment cycles (\$13.97, \$12.79, and \$10.21 respectively). Public sector and “other” medical sector costs drop noticeably over the same treatment cycle. Interestingly, health care costs within the various health sectors have swapped positions from the 2000 CDHS to the 2005 CDHS. In the 2000 CDHS, the public and “other” sectors vied for top spots as most expensive, whereas in the 2005 CDHS, the private sector is consistently the most expensive treatment. Overall, however, costs have dropped considerably from the 2000 CDHS, with public sector costs dropping by half (from \$31.90 overall to \$15.52) and private sector costs dropping by 31 percent (from \$27.10 overall to \$18.62). The “other” sector has dropped the most significantly, almost five-fold, from \$55.90 in the 2000 CDHS to \$10.94 in the 2005 CDHS.

For health care costs, the most expensive total cost was for treatment within the private sector (\$17.98), while the lowest was for those who sought care within the non-medical sector (\$5.76). This is true for all orders of treatment.

Note: Table includes only persons who paid cash or who reported no cost. All costs cited in US dollars. One US dollar = 4,000 Riels. Total includes 12 persons for whom information on severity of illness is not available. Figures in parentheses are based on 25-49 unweighted cases. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.

In general, health care costs rose significantly by severity of illness or injury. The total mean costs of treatment increased from \$3.13 for slight illness or injury to \$47.17 for serious conditions. This follows the same trend established in the 2000 CDHS, though as noted above, overall costs have decreased since then (\$4.60 for slight illness or injury to \$61.70 for serious illnesses in the 2000 CDHS).

Total health care costs rise by the patient's age, ranging from \$5.72 for children age 0-9 to \$20.70 for people age 60 years and older. Health care expenditures by sex have become more equitable since the last CDHS, though spending patterns by sex have changed roles. In 2000, men spent less than women for total health care (\$18.40 compared with \$20.20), whereas in 2005, men spent more than women on total health care (\$14.09 compared with \$13.91).

Total health care costs have remained more expensive in the urban areas than the rural areas since the 2000 CDHS, with the cost in urban areas staying the same (from \$22.70 in 2000 compared with \$22.89 in 2005). The cost in rural areas dropped by a third (from \$18.90 in 2000 compared with \$12.76 in 2005). On the other hand, transport costs have made an about face. In the 2000 CDHS, total transport costs were more than twice as expensive in urban areas than in rural areas (\$3.20 compared with \$1.20 respectively), whereas transport costs now are less in urban areas than in rural areas (\$0.94 in versus \$1.17 respectively).

Health care expenditures vary greatly in Cambodia's provinces. The most expensive cost for health care is in Krong Preah Sihanouk/Kaoh Kong (\$43.61) and the least expensive is in Preah Vihear/Steung Treng (\$5.48). As Kaoh Kong has limited services and is located on the border with Thailand, it is possible that the high health expenditures reflect care sought across the border.

As the health care system in Cambodia is a largely a fee-based system, it is important to know the source of the money used to pay for health care. One goal of the health care system is to have appropriate funding mechanisms for the population to acquire health care without deepening poverty. Table 3.9 shows that 45 percent of the money spent on health care came from wages/pocket money and 30 percent from savings. This is drastically different from the situation during the 2000 CDHS, where barely 16 percent of the money spent on health care came from wages/pocket money and 54 percent came from savings.

There are small differences in the source of money spent on health care by type of health sector. In all sectors, wages/pocket money is the most common source of funding (42 percent to 65 percent), followed by savings (20 percent to 32 percent). Borrowed money with interest is the next most common source of funding for public and private sector health care (8 percent). The same is true for borrowed money without interest (6 percent). Overall, borrowed money has dropped as a total source of money since the 2000 CDHS. For example, in the 2000 CDHS, borrowed money (with interest) was cited 10.9 percent of the time, whereas in the 2005 CHDS it was cited just 7.4 percent of the time. A similar drop occurred with borrowed money (no interest), showing a drop from 8.6 percent in 2000 to 5.5 percent in 2005. Additionally, selling assets to obtain money to pay for health care dropped from 6.2 percent in 2000 to 2.7 percent in 2005. This would indicate that people are now better able to afford health care by their own means than before.

The source of money for treatment varies by the severity of illness or injury, though following the same trend established in the 2000 CDHS. Wages/pocket money and savings were the most common source of money for care for the slight illnesses. With severe illnesses, the source shift to borrowed money with interest (from 3 percent for slight illness to 18 percent for severe illness) as did borrowed money without interest (from 3 percent for slight illness to 9 percent for severe illness).

Table 3.9 Source of money spent on health care

Percent distribution of the source of expenditures for transport and health care according to background characteristics, Cambodia 2005

Background characteristic	Source of money for health care								Total	Number
	Wages/ pocket money	Gift from relative/ friend	Savings	Borrowed money (no interest)	Borrowed money (with interest)	Sold assets	Other	Missing

Mondol Kiri/Rattanak Kiri	2.5	0.6	77.1	11.0	5.0	2.2	0.4	1.2	100.0	95
Total	45.0	6.1	30.3	5.5	7.4	2.7	2.8	0.2	100.0	7,050

Note: Total includes 7 persons for whom information on severity of illness is not available and 5 persons for whom information on cost of treatment and transport is not available.

The monetary costs of health care treatment shows a similar pattern as to those described above. Wages/pocket money and savings were the most important sources of money for health costs under \$99.00, with the percentage from these two sources decreasing as the costs increased. Borrowed money (with interest) became the most important source of money for treatment costs of \$100.00 or more, with fully 25 percent coming from this source.

There were no real differences in the source of money for health care costs by virtue of the patient's sex. Urban residents were more likely than rural residents to use wages or pocket money for health care (61 percent compared with 43 percent). On the other hand, rural residents were more likely than urban residents to pay the health care with their savings (32 percent compared with 21 percent).

Large differences were found in the sources of money for health care costs by province. Patients in Otdar Mean Chey were the most likely to use their wages or pocket money to pay for their health care (81 percent) and the least likely to use their savings (1.4 percent). Seam Reap was not far behind with 70 percent of health care costs being covered from wages and pocket money and 11 percent covered from savings. This is vastly improved from the 2000 CDHS, when these combined provinces spent only devoted 3.1 of their wages and pocket money towards health care costs yet 63 percent of their savings.

Conversely, Kampot/Krong Kep had the highest reliance on savings for health care spending (86 percent) and the lowest reliance on wages/pocket money (1.6 percent). Mondol Kiri/Rattanak Kiri followed closely with a 77 percent reliance on savings and a 2.5 percent reliance on wages/pocket money. As in 2000, patients with the highest reliance on borrowed money (with interest) for health care were in Banteay Mean Chey (27 percent). It is interesting to note that patients in Prey Veng relied on “other” sources of money (19 percent) for their health care costs much more significantly than any other province.

RESPONDENT CHARACTERISTICS

This chapter provides a demographic and socioeconomic profile of respondents interviewed in the 2005 CDHS. Such background information is essential to the interpretation of findings and for understanding the results presented later in the report. Basic characteristics collected include age, level of education, marital status, religion, and wealth status. Exposure to mass media and literacy status were examined, and detailed information was collected on employment status, occupation, and earnings. In addition, the CDHS collected data on knowledge and attitudes concerning tuberculosis and use of tobacco.

4.1 CHARACTERISTICS OF SURVEY RESPONDENTS

The background characteristics of the 16,823 women age 15-49 and the 6,731 men age 15-49 interviewed in the 2005 CDHS are shown in Table 4.1. This table is important in that it provides the background for interpreting findings presented later in the report.

The distribution of the population of women and men by age reflects recent Cambodian history. Note that 21 percent of women and 25 percent of men fall into the 15-19 age group while 18 percent of women and men fall into the 20-24 age group. Significantly smaller proportions of women and men are found in the older age groups. Twelve to 13 percent of women and men fall into the five-year age groups between 25 and 44, and 10 percent of women and 8 percent of men fall into the 45-49 age group. This unusual distribution of respondents into the youngest age groups is an indicator of the demographic shocks that occurred as a result of the Khmer Rouge regime (1975-1979). Fertility declined during these years, concomitant with higher than normal mortality due to national conflict. Between one and two million people are estimated to have been killed during the reign of the Khmer Rouge. These events are reflected in the smaller than expected proportions of women and men in the 25-29 and 30-34 age groups. After the conflict subsided, there was a baby boom, represented by the high proportion of women and men in the 15-19 and 20-24 age groups.

The majority of surveyed respondents (60 percent of women and 59 percent of men) are married or living together. The proportion not currently married varies by gender. Three in ten women has never married compared with four in ten men. On the other hand, women are much more likely to be divorced, separated, or widowed (8 percent) than men (2 percent).

Place of residence is another characteristic that determines access to services and exposure to information pertaining to reproductive health and other aspects of life. The majority of respondents reside in rural areas, with only 18 percent of women and 17 percent of men residing in urban areas. Thirteen percent of men and women live in Kampong Cham, and 11 percent live in the capital city of Phnom Penh. Cambodians are predominantly Buddhist, while 2 percent are Muslim and less than 1 percent are Christian.

The majority of Cambodians have some formal schooling. The education level of women has improved since the 2000 CDHS. The percentage of women who never attended school declined from 28 percent in the 2000 survey to 19 percent in 2005. At the same time, the percentage of women who attended any secondary school increased from 17 percent to 25 percent. However, Table 4.1 shows there are still notable differences in educational attainment of women and men. Twice as many women as men have never attended school (19 percent of women compared with 9 percent of men), and only a little over half as many women as men have attended secondary school (25 percent versus 43 percent).

Note: Education categories refer to the highest level of education attended, whether or not that level was completed.

4.2 EDUCATIONAL ATTAINMENT AND LITERACY

Tables 4.2.1 and 4.2.2 present detailed distribution of educational attainment, according to background characteristics. The general pattern evident in Table 4.2.1 indicates a decrease in the proportion of women with no education from the oldest to the youngest cohorts. Women in the 40-44 age group are an exception to this trend; a higher percentage of women age 40-44 have never been to school compared with women in the 45-49 age group (35 versus 30 percent). This pattern probably occurred because women in the 40-44 age group reached school age at the time of the Khmer Rouge. Men in the 40-44 age group exhibit the same pattern. Women born during the reign of the Khmer Rouge (those currently age 25-29) are also somewhat more likely than the surrounding age groups to have no formal education. Men born during the time of the Khmer Rouge as well as those born just before (men currently age 25 to 34) are also more likely to have never attended school. The data presented in Tables 4.2.1 and 4.2.2 provide evidence of an increase in educational attainment among the youngest age cohort. For example, two in five women age 15-19 have attended some secondary school as compared with only one in five women age 20-24.

Urban women are more highly educated than rural women. One-third of urban women have attended some secondary school compared with 19 percent of rural women. Table 4.2.1 shows great variation in education across provinces. Mondol Kiri and Rattanak Kiri have an exceptionally low rate of school attendance among women. Three in five women have no formal education. By contrast, only one in ten women in Phnom Penh has never attended school. The median grade attained is highest in Phnom Penh, Kandal, and Takeo (5.9, 4.5 and 4.1, respectively).

Educational attainment rises dramatically with wealth quintile. Almost two in five women in the lowest quintile have no formal education (37 percent) compared with less than one in ten women in the highest wealth quintile (7 percent). The percentage of women who have attended some secondary school increases from 5 percent in the lowest wealth quintile to 41 percent in the highest. The pattern of variation in educational attainment by province and wealth among men is similar to that of women.

The 2005 CDHS assessed literacy levels among women who had never been to school or who had attended only the primary level by asking them to read all or part of a sentence in whatever language the respondent was familiar. Those who had attained middle school or above were assumed to be literate.

Table 4.2.1 Educational attainment: women

Percent distribution of women by highest level of schooling attained, and median grade completed, according to background characteristics, Cambodia 2005

Background characteristic	Highest level of schooling attended or completed						Total	Number of women	Median grade

Table 4.3 shows that seven in ten women in Cambodia are literate. Literacy is associated with access to education. In general, the younger age groups are more likely to be literate than the older age groups. Illiteracy decreases from 38 percent among women age 45-49 to 16 percent among women age 15-19. However, illiteracy is higher among women in the 25-29 and 40-44 age groups than in the surrounding age cohorts. As seen in Table 4.2.1, these women were less likely to have attended school than the age cohorts before and after them.

Table 4.3 Literacy: women

Percent distribution of women by level of schooling attended and level of literacy, and percent literate, according to background characteristics, Cambodia 2005

¹ Refers to women who attended secondary school or higher and women who can read a whole sentence or part of a sentence

Four in five women residing in urban areas are literate compared with two in three of their rural counterparts. Differences in literacy across provinces are marked, with literacy being highest among women in Phnom Penh (87 percent) and lowest in Mondol Kiri and Rattanak Kiri (33 percent). Literacy levels increase along with women's wealth status, doubling from 45 percent among women in the lowest wealth quintile to 90 percent among women in the highest wealth quintile.

There has been little change in the overall illiteracy rate since the 2000 CDHS (32 percent in 2000 compared with 30 percent in 2005). However, there has been a large decrease in illiteracy in the 15-19 age group from 25 percent to 16 percent, reflecting the increase in the level of educational attainment in this cohort since the previous survey (see Table 4.2.1).

4.3 ACCESS TO MASS MEDIA

The 2005 CDHS collected information on the exposure of respondents to both broadcast and print media. This information is important because it provides an indication of the exposure of women to mass media that can be used to disseminate family planning, health, and other information. Access to mass media is relatively high in Cambodia. Table 4.4.1 shows that four in five women have some weekly exposure to the mass media. Watching television is the most common way of accessing the media: 68 percent of women watch television at least once a week. Listening to the radio is also common (half of women listen at least once a week), with newspapers being the least utilized form of media (13 percent read a newspaper at least once a week).

Background characteristic	Reads a newspaper at least once a week	Watches television at least once a week	Listens to the radio at least once a week	All three media at least once a week	No media at least once a week	Number of women
Age						
15-19	19.4	78.1	57.1	14.1	13.5	3,601

Highest	35.8	91.9	61.9	26.9	4.0	4,089
Total	13.4	68.0	50.2	9.5	21.1	16,823

There is no strong trend in access to the three types of media by age. The youngest group of women (15-19 years old) is most likely to access each form of media, particularly television and newspaper. However, women in the oldest age group are not always the least likely to access media. Women in the 40-44 age group are least likely to read a newspaper at least once a week (8 percent) while women ages 30-34 are least likely to watch television or listen to the radio (62 percent and 42 percent, respectively).

Residence, on the other hand, is associated with clear differences in media exposure. Urban women have better access to all three media sources than their rural counterparts. Due to lower literacy levels, rural women are much less likely to report that they read a newspaper at least once a week than urban women (9 percent compared with 33 percent).

Among the provinces, women residing in Phnom Penh have by far the greatest exposure to all three media (28 percent), with Battambang and Krong Pailin being the next provinces most exposed to mass media with 18 percent of women using all three types of media at least once a week. Women residing in Mondol Kiri and Rattanak Kiri, Otdar Mean Chey, and Preah Vihear and Steung Treng are the least likely to be exposed to the media (66 percent, 58 percent, and 56 percent, respectively, have no weekly access to media).

Media exposure increases with both the educational level and wealth quintile of the respondent. For example, 92 percent of women in the highest wealth quintile watch television at least once per week compared with 37 percent of women in the lowest wealth quintile. Regarding the printed media, 10 percent of women with primary education reported reading a newspaper at least once a week, compared with 32 percent of women with secondary and higher education.

A comparison of Tables 4.4.1 and 4.4.2 shows that women are somewhat more likely than men not to access media at least once per week (21 percent of women compared with 18 percent of men). Most of this difference is explained by greater access of men to radio: 60 percent of men listen to the radio at least once per week compared with 50 percent of women.

There has been an increase in exposure to the media since 2000, especially in areas outside of Phnom Penh. The proportion of women who do not access any form of media at least once a week declined from 30 percent in the 2000 CDHS to 21 percent in the 2005 survey. The greatest increase has come in the proportion of women who watch television at least once a week (56 percent in 2000 compared with 68 percent in 2005).

Table 4.4.2 Exposure to mass media: men

Percentage of men who are exposed to specific media on a weekly basis by background characteristics, Cambodia 2005

4.4 EMPLOYMENT

Employment Status

In the 2005 CDHS, respondents were asked a number of questions regarding their employment status, including whether they did any work in the seven days preceding the survey and, if not, whether they had worked in the 12 months before the survey. The results for women and men are presented in Tables 4.5.1 and 4.5.2. At the time of the survey, two-thirds of women (64 percent) were currently employed and an additional 15 percent were not employed but had worked sometime during the preceding 12 months (Figure 4.1). The proportions currently employed generally increase with increasing age. Women who are divorced, separated, or widowed are more likely to be employed than other women.

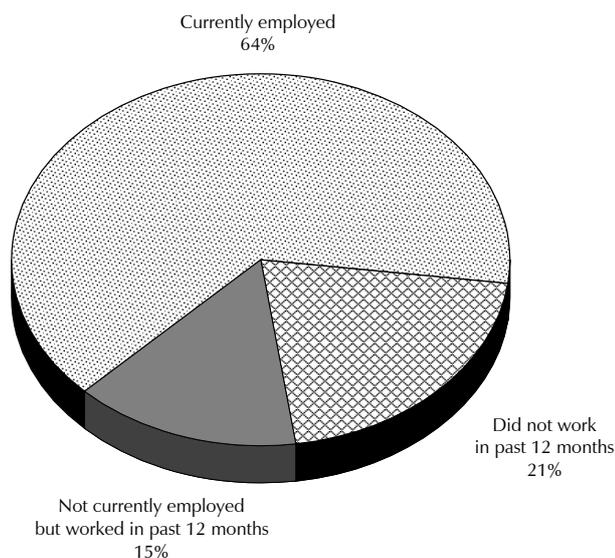

Table 4.5.1 Employment status: women

Percent distribution of women by employment status, according to background characteristics, Cambodia 2005

Background characteristic	Employed in the 12 months preceding the survey		Not employed in the 12 months preceding the survey	Missing	Total	Number of women

¹ "Currently employed" is defined as having done work in the past seven days. Includes persons who did not work in the past seven days but who are regularly employed and were absent from work for leave, illness, vacation, or any other such reason.

Figure 4.1 Women's Employment Status in the Past 12 Months

CDHS 2005

Urban and rural women are roughly equally likely to be currently employed (60 percent compared with 65 percent). However, rural women are more likely than urban women to have worked in the past 12 months but not in the last seven days. As a result urban women are more likely than rural women not to have been employed at all in the 12 months preceding the survey (31 percent vs. 19 percent). Women in Kampong Cham, Kampong Chhnang, Kandal and Svay Rieng are most likely to be currently employed (73 percent). In contrast, women in Phnom Penh, Krong Preah Sihanouk and Kaoh Kong, and Kratie are most likely not to have been employed at any time in the 12 months preceding the survey (35 percent, 32 percent, and 31 percent, respectively).

Women with some secondary education and those in the highest wealth quintile are least likely to have worked in the 12 months preceding the survey.

The proportion of men currently employed is higher than that of women (79 percent compared with 64 percent). As with women, urban men are more likely not to have worked in the 12 months preceding the survey, as are men with secondary education or higher and those in the highest wealth quintile. The proportion of men currently employed ranges from 6 in 10 men in Pursat being currently employed, to 9 in 10 men in Kampong Cham being currently employed. Men were most likely to have worked at some point in the 12 previous months in Mondol Kiri and Rattanak Kiri and least likely to have done so in Phnom Penh.

The level of female employment is lower in 2005 than in 2000. The difference in the percentage of women currently employed between 2000 (73 percent) and 2005 (64 percent) may be due to a difference in the way the data on current employment were collected in the two DHS surveys. The difference in the level of women not employed in the 12 months preceding the survey between the two surveys is smaller: 18 percent in 2000 compared with 21 percent in 2005.

Occupation

Respondents who were currently employed or had worked in the 12 months preceding the survey were further asked to specify their occupation. Tables 4.6.1 and 4.6.2 show data on occupation of employed women and men, respectively. Most employed persons are engaged in the agricultural sector, including 59 percent of women and 63 percent of men. Over one-quarter of women are employed in sales and services as well as about 12 percent of men. Five percent of women are employed in skilled manual labor and 5 percent are employed in unskilled manual labor. Less than 3 percent of women are employed in professional, technical, and managerial fields.

Highest	12.5	7.5	32.7	25.4	6.5	13.9	1.5	100.0	1,211
Total 15-49	5.0	1.9	11.6	11.0	6.8	62.6	1.1	100.0	5,641

Residence has a significant effect on the type of occupation. Women and men in urban areas are more likely to hold jobs in the professional, technical, and managerial, clerical, and sales and services sectors than are those in rural areas. Rural women and men, on the other hand, are more likely than those in urban areas to be engaged in agricultural work. Those with less education and in lower wealth quintiles are also more likely to work in agriculture.

Since the 2000 CDHS, the percentage of women working in agriculture has decreased from 67 percent to 59 percent while the percentage working in sales and services has increased from 20 percent to 26 percent.

Earnings, Employers and Continuity of Employment

Table 4.7 shows the percent distribution of employed women by type of earnings and employment characteristics. The table takes into account whether women are involved in agricultural or nonagricultural occupations, because all of the employment variables in the table are strongly influenced by the sector in which a woman is employed.

Table 4.7 Type of employment			
Percent distribution of women employed in the 12 months preceding the survey by type of earnings, type of employer, and continuity of employment, according to type of employment (agricultural or nonagricultural), Cambodia 2005			
Employment characteristic	Agricultural work	Nonagricultural work	Total
Type of earnings			
Cash only	17.8	92.8	48.2
Cash and in-kind	14.6	1.4	9.2
In-kind only	59.9	1.5	36.2
Not paid	7.5	4.2	6.2
Missing	0.1	0.1	0.1
Total	100.0	100.0	100.0
Type of employer			
Employed by family member	47.8	20.3	36.7
Employed by nonfamily member	10.7	32.9	19.6
Self-employed	41.5	46.7	43.6
Missing	0.0	0.1	0.0
Total	100.0	100.0	100.0
Continuity of employment			
All year	6.8	79.5	36.4
Seasonal	91.7	14.4	60.3
Occasional	1.5	6.0	3.3
Missing	0.0	0.1	0.1
Total	100.0	100.0	100.0
Number of women employed during the past 12 months	7,874	5,302	13,261

Note: Total includes women with missing information on type of employment who are not shown separately.

Three in five women engaged in agricultural work are paid in-kind, around one in five is paid in cash only, 15 percent are paid in cash and in-kind, and 8 percent are unpaid. Women employed in the nonagricultural sector are more likely to be paid in cash (93 percent). Nationally, across all occupations, almost half (48 percent) of employed women are paid in cash and 36 percent are paid in-kind for their work.

Four in 10 employed women are self employed, and 37 percent are employed by a family member. One in five employed women works for someone outside the family.

Among women working in the agricultural sector, almost half (48 percent) are working for a family member compared with one-fifth of those in the nonagricultural sector. In addition, the proportion of women employed by someone outside the family is three times higher among those working in the nonagricultural sector than those in the agricultural sector (33 percent versus 11 percent).

Generally, 36 percent of employed women work all year round while three in five employed women work seasonally. Those who work occasionally account for only 3 percent. Among women working in the agricultural sector, around nine in ten are seasonal workers compared with only 14 percent of those working in the nonagricultural sector. Continuity of employment is more assured for women engaged in nonagricultural work than those in agricultural work. For example, 4 in 5 women working in the nonagricultural sector work all year compared with only 7 percent of women engaged in agricultural work.

4.5 KNOWLEDGE AND ATTITUDES CONCERNING TUBERCULOSIS

Tuberculosis (TB) is a leading cause of death in the world and a major health problem in the developing world. TB is caused by the bacteria *mycobacterium tuberculosis* whose transmission is mainly airborne through droplets coughed or sneezed out by infected persons. The infection is primarily concentrated in the lungs but in some cases it can be transmitted to other areas of the body. The very young and very old and persons with a suppressed immune system (brought on from HIV infection or other causes) are especially prone to contracting the disease when exposed to it. The 2005 CDHS collected information from women on the level of their awareness of TB. Specifically, respondents were asked whether they had ever heard of the illness, how it spreads from one person to another, whether it can be cured, and whether they would want to keep the information secret if a member of their family got TB. This information is useful in policy formulation and implementation of programmes designed to combat and limit the spread of the disease.

Table 4.8 shows the percentage of women who have heard of TB, and among those who have heard of it, their knowledge and attitudes concerning TB, according to background characteristics. Knowledge of TB is almost universal among women in Cambodia (97 percent). There is very little variation in awareness by background characteristics, although knowledge of TB does increase somewhat with educational attainment and wealth quintile. For example, 93 percent of women with no formal education have heard of TB compared with 99 percent of women with secondary education or higher. Knowledge of TB is over 90 percent in all provinces with the exception of Preah Vihear and Steung Treng (89 percent) and Mondol Kiri and Rattanak Kiri (69 percent).

Two in three women (64 percent) who know of TB reported that it is spread through the air when coughing or sneezing. Knowledge of how TB is spread slightly decreases with increasing age and slightly rises with educational attainment. Generally, knowledge of the way TB is spread increases with wealth quintile; however, women in the fourth wealth quintile are more likely to know how TB is spread than women in the highest wealth quintile (73 percent versus 66 percent). Correct knowledge of how TB spreads varies widely across provinces, ranging from 39 percent in Banteay Mean Chey to 94 percent in Otdar Mean Chey.

Eighty-four percent of women believe that TB can be cured. Women's belief that TB can be cured varies by education, wealth quintile, and province. More than nine in ten women (92 percent) with some secondary education or higher believe that TB can be cured compared with three-quarters of women with no education. Women in the top two wealth quintiles are more likely to believe that TB can be cured than those in the lowest three quintiles. Belief that TB can be cured is highest in Battambang and Krong Pailin (95 percent) and lowest in Mondol Kiri and Rattanak Kiri (62 percent).

Wanting to keep a family member's illness secret is a sign of stigma against persons with TB. Only 13 percent of women in Cambodia say they would want to keep secret a family member's TB illness. Younger women and women living in urban areas are slightly more likely to want to keep the illness secret.

Table 4.8 Knowledge and attitude concerning tuberculosis: women

Percentage of women who have heard of tuberculosis (TB), and among women who have heard of TB, the percentage who know that TB is spread through the air by coughing, the percentage who believe that TB can be cured, and the percentage who would want to keep secret that a family member has TB, by background characteristics, Cambodia 2005

Background characteristic	Among all women:		Among women who have heard of TB:			
	Percentage who have heard of TB	Number of women	Percentage who report that TB is spread through the air by coughing	Percentage who believe that TB can be cured	Percentage who would want a family member's TB kept secret	Number of women

4.6 USE OF TOBACCO

Smoking or other use of tobacco affects women's health and may adversely affect their children's health, especially in terms of vulnerability to respiratory illness. In addition, tobacco use during pregnancy increases the risk of having a small or low birth weight baby. Women interviewed in the 2005 CDHS were asked about their smoking habits. Table 4.9 shows the percentage of women who use various types of tobacco and the percent distribution of cigarette smokers by number of cigarettes smoked in the preceding 24 hours, according to background characteristics.

Overall, 11 percent of women in Cambodia use some form of tobacco. Four percent smoke cigarettes and 8 percent use a form of tobacco other than cigarettes or a pipe (some women use more than one form of tobacco). Among pregnant women, 8 percent use tobacco, and 12 percent of women who are breastfeeding do so. Tobacco use varies greatly by background characteristics. Older women are much more likely to use tobacco than are younger women. Cigarette smoking increases from less than 1 percent among women age 15-19 to 7 percent among women 45-49 while use of tobacco other than cigarettes or pipe increases from close to zero to 27 percent among women in these same age groups.

Women in rural areas, those with less education and those in lower wealth quintiles are more likely to use tobacco. Only 4 percent of women in urban areas use tobacco compared with 12 percent of women in rural areas. Tobacco use ranges from 1 percent among women with secondary education and 2 percent among women in the highest wealth quintile to 22 percent among women with no education and 24 percent among those in the lowest wealth quintile. Tobacco use is highest in Mondol Kiri and Rattanak Kiri where four in ten women use tobacco, mostly in the form of cigarettes, and in Preah Vihear and Steung Treng (28 percent) where the proportions of women smoking cigarettes and using other forms of tobacco are both high.

Table 4.9 Use of tobacco: women

Percentage of women who smoke cigarettes or a pipe or use other tobacco products and the percent distribution of cigarette smokers by number of cigarettes smoked in preceding 24 hours, according to background characteristics and maternity status, Cambodia 2005

Note: Figures in parentheses are based on 25-49 unweighted cases. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.

Fertility is an important component of population dynamics and plays a large role in changing the size and structure of the population of a given area. Cambodia is a country in which population size and structure were severely impacted during the reign of the Khmer Rouge (1975-1979), both in terms of excess mortality as well as reduced fertility. The Cambodia DHS survey generates detailed information on fertility and fertility patterns over time that will be useful for the formulation of policies and the design of programs.

Current fertility levels, trends and differentials in fertility, cumulative fertility, birth intervals, age at first birth, and adolescent fertility are examined in this chapter. The fertility indicators presented in this chapter are based on information obtained from women age 15-49. All women who were interviewed in the 2005 CDHS were asked to report the total number of daughters and sons they had ever given birth to in their lifetime. To encourage complete reporting, women were asked separately about children still living at home, those living elsewhere, and those who had died. A complete birth history was then obtained, including information on the sex, date of birth,¹ and survival status of each child, and the age at death for dead children.

5.1 CURRENT FERTILITY LEVELS AND DIFFERENTIALS

The current level of fertility refers to live births in the three-year period preceding the survey. This information was obtained from birth history data and is presented in Table 5.1. The summary measures include age-specific fertility rates (ASFRs),² total fertility rates (TFRs) for women age 15-49, the general fertility rate (GFR), and the crude birth rate (CBR). The ASFRs represent the number of live births per 1,000 women in the age group. The TFR is a common measure of current fertility and is defined as the total number of births a woman would have by the end of her childbearing years if she were to pass through those years bearing children at the currently observed age-specific fertility rates. The GFR is defined as the annual number of births per 1,000 women age 15-44. The CBR is the total number of births occurring in a given year per 1,000 population.

Table 5.1 Current fertility

Age-specific and total fertility rates, general fertility rates, and crude birth rates for the three years preceding the survey, by residence, Cambodia 2005

Age group	Residence		Total
	Urban	Rural	
15-19	32	51	47
20-24	133	185	175
25-29	139	188	180
30-34	134	143	142
35-39	71	94	91
40-44	47	40	41
45-49	2	5	5
TFR (15-49)	2.8	3.5	3.4
GFR	89	115	111
CBR	23.8	25.9	25.6

Note: Age-specific fertility rates are per 1,000 women. Rates for age group 45-49 may be slightly biased due to truncation.

TFR: Total fertility rate expressed per woman
 GFR: General fertility rate (births divided by the number of women age 15-44), expressed per 1,000 women

CBR: Crude birth rate expressed per 1,000 population

¹ During data collection, interviewers recorded Gregorian month and year of birth. However, when the respondent only knew the Khmer month and year of birth, the interviewer used a chart specially designed for the CDHS survey to convert Khmer dates into Gregorian dates.

² Numerators of the three-year ASFRs are calculated by summing the number of live births that occurred in the period 1-36 months preceding the survey (determined by the date of interview and the date of birth of the child) and classifying them by age (in five-year groups) of the mother at the time of birth (determined by the mother's birth date). The denominators of the rates are the number of woman-years lived in each of the specified five year age groups during the 1-36 months preceding the survey.

The total fertility rate in Cambodia for the three years preceding the survey indicates that if fertility rates were to remain constant at the level prevailing during the period 2003-2005 a Cambodian woman would bear 3.4 children during her lifetime. The average Cambodian woman will give birth to 1.1 children by age 25³ and 2.0 children by age 30. The TFR in urban areas is 2.8 births per woman, almost one child lower than the rate in rural areas (3.5 births per woman). An examination of the age-specific rates by urban-rural residence indicates that while the age pattern of fertility is generally the same in urban and rural areas, fertility rates are higher in nearly every age group for rural women as compared with urban women. Among women age 15-19, fertility rates are quite low in both urban and rural areas (32 and 51 per 1,000 women, respectively). Rates then increase to reach their maximum among women age 25-29 (139 and 188 per 1,000 urban and rural women, respectively). Above the age of 29, rates decline slowly but regularly in both urban and rural areas.

The CBR, also presented in Table 5.1, is 25.6 per 1,000 population. The GFR is 111 per 1,000 women age 15-44 for the three years prior to the survey. Like the TFR, the GFR and CBR also vary by urban-rural residence. Thus, with a GFR of 115, the average annual number of births to rural women is nearly one-third higher than that for urban women (89 births per 1,000 women). The CBR in rural areas (25.9 per 1,000) is somewhat higher than the CBR in urban areas (23.8 per 1,000).

Table 5.2 presents differentials in fertility by urban-rural residence, province, education, and wealth quintile. There are large differences in fertility levels across provinces. Fertility is lowest in the capital city of Phnom Penh, at 2.5 children per woman and highest in Mondol Kiri/Rattanak Kiri at 5.2 children per woman. Among the remaining provinces, total fertility ranges from 3.0 to 4.9. Fertility is well known to be inversely related to level of education around the world and Cambodian women are demonstrating this universal pattern. A woman with no education (TFR of 4.3) has 0.8 children more than a woman with primary education (TFR of 3.5), who herself has one child more than a woman with some secondary education (TFR of 2.6).

³ Calculated as the age-specific fertility rate for women 15-19 plus the age-specific fertility rate for women 20-24, multiplied by 5 (to take into account the five-year age group), divided by 1,000.

Table 5.2 Fertility by background characteristics

Total fertility rate for the three years preceding the survey, percentage of women currently pregnant, and mean number of children ever born to women age 40-49, by background characteristics, Cambodia 2005

Background characteristic	Total fertility rate	Percentage currently pregnant	Mean number of children ever born to women age 40-49
Residence

Total	3.4	5.9	4.9

5.2 FERTILITY TRENDS

The 2005 CDHS data can be used to assess the trend in fertility in Cambodia in several ways.

Comparison of Current and Cumulative Fertility Levels

Table 5.2 also allows a crude assessment of trends in the various subgroups by comparing current fertility with a measure of completed fertility: the mean number of children ever born to women age 40-49. The mean number of children ever born to older women who are nearing the end of their reproductive period is an indicator of average completed fertility of women who began childbearing during the three decades preceding the survey. If fertility remained constant over time and the reported data on both children ever born and births during the three years preceding the survey are reasonably accurate, the TFR and the mean number of children ever born to women 40-49 would be equal. When fertility levels have been falling, the TFR will be substantially lower than the mean number of children ever born among women age 40-49. Comparison of the mean number of children

ever born to women age 40-49 (4.9) with the TFR (3.4) suggests a decline of about one and one-half children per woman in Cambodia over the past few decades. Fertility has declined in both rural and urban areas, in all provinces, at all educational levels, and for all wealth quintiles. The differences between the level of completed and current fertility are of similar magnitude in urban (1.4) and rural areas (1.6). The largest observed differences are in Pursat and Kandal, with a decrease of 2 children per woman. While all provinces demonstrate declines in fertility, it has only decreased by half a child per woman in Kampong Chhnang.

Table 5.2 includes another indicator of current fertility, the percentage of women who reported being pregnant at the time of the survey. This percentage may be underreported since women may not be aware of a pregnancy, especially at the very early stages, and some women who are early in the pregnancy may not want to reveal that they are pregnant. Six percent of women reported that they were pregnant at the time of the survey. The proportion of pregnant women is lower in urban areas (4 percent) than in rural areas (6 percent). Phnom Penh and Takeo have the lowest proportion currently pregnant (4 percent), whereas the highest proportion pregnant is reported in Mondol Kiri/Rattanak Kiri (10 percent). The proportion of women currently pregnant declines steadily with increasing education and increasing wealth quintile.

Retrospective Data

Fertility trends can be investigated using retrospective data from the birth histories collected within the 2005 CDHS. Table 5.3.1 shows ASFRs for successive five-year periods preceding the 2005 CDHS. Numerators of the rates are classified by five-year segments of time preceding the survey and the mother's age at the time of the survey. Because women 50 years and over were not interviewed in the survey, the rates for older age groups become progressively more truncated for periods more distant from the survey date. For example, rates cannot be calculated for women age 35-39 for the period 15-19 years before the survey because these women would have been over age 50 at the time of the survey and were not interviewed.

Table 5.3.1 Trends in age-specific fertility rates

Age-specific fertility rates for five-year periods preceding the survey, by mother's age at the time of the birth, Cambodia 2005

Mother's age at birth	Number of years preceding survey			
	0-4	5-9	10-14	15-19
15-19	52	65	85	58
20-24	178	205	243	228
25-29	177	211	261	276
30-34	139	176	231	[272]
35-39	94	132	[180]	
40-44	41	[77]		
45-49	[5]			

Note: Age-specific fertility rates are per 1,000 women. Estimates in brackets are truncated.

Age-specific fertility rates calculated over time from the 2005 CDHS provide further evidence of a substantial decline in fertility at all ages. Fertility declines are proportionately greater, however, for women aged 30 and older than for women in the prime childbearing ages of 20-29 years. Women age 30 and above experienced more than a 20 percent decline in fertility in the five years preceding the survey. This pattern is common in populations experiencing a fertility decline. It occurs during a fertility transition when older women, who may be more likely to have reached their desired family size, make a greater effort to limit their births than do younger women, who are likely to have not yet achieved their desired family size. What is more unusual is that there has also been a 20 percent decline in fertility among women age 15-19, suggesting that women are waiting later to begin childbearing.

Comparison with Previous CDHS

Another way to assess fertility trends is to compare current estimates with earlier surveys. Table 5.3.2 and Figure 5.1 show the ASFRs for both the 2000 CDHS and the 2005 CDHS. The current TFR of 3.4 attests to a fairly sharp decline in fertility, from 4.0 children per woman reported in the 2000 CDHS. While fertility declined in both urban and rural areas, the change in the TFR between the 2000 CDHS and the 2005 CDHS occurred predominantly as a result of declining fertility among rural women. The TFR decreased by 0.7 children among rural women and by 0.3 children among urban women.

Declines in ASFRs between 2000 and 2005 have occurred among all age groups. The age groups in which women have demonstrated the largest decreases in fertility are 25-29, 30-34 and 35-39, with women in the 35-39 age group showing a decrease of 27 births per thousand women, and the women in the other two age groups demonstrating a decrease of 23 births per thousand women. Fertility has fallen in nearly all provinces as well, including the highest fertility provinces of Mondol Kiri/Rattanak Kiri where the TFR has declined by one child from 6.3 to 5.2. The TFR has risen, however, in Phnom Penh from 2.1 to 2.5 children.

Table 5.3.2 Trends in age-specific and total fertility rates

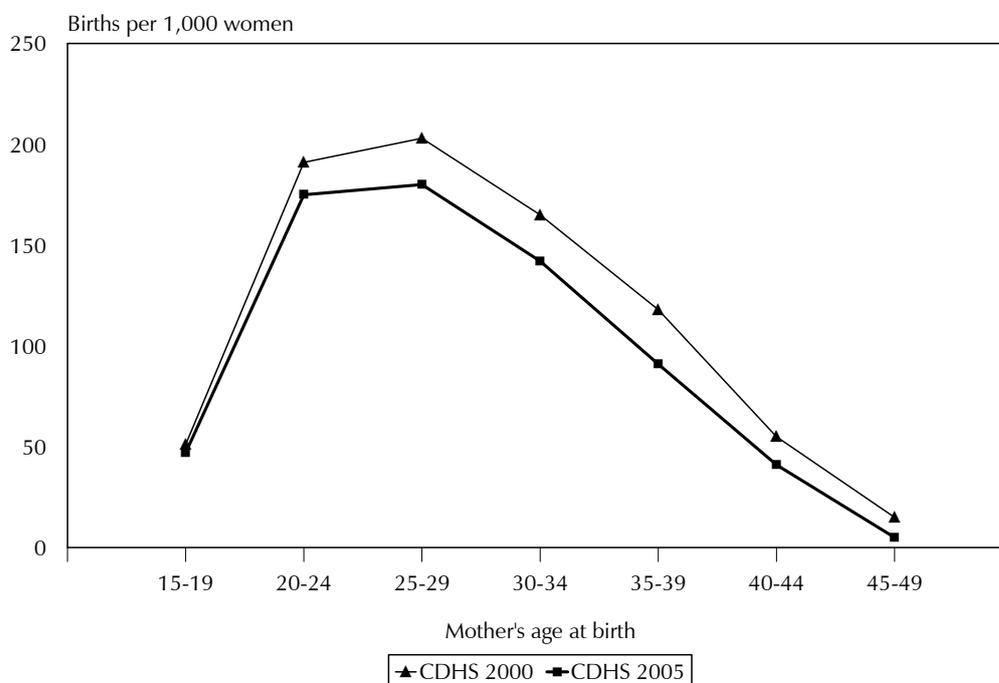

Age-specific and total fertility rates (TFR), Cambodia 2000 and Cambodia 2005

Mother's age at birth	CDHS 2000 ¹	CDHS 2005
15-19	51	47
20-24	191	175
25-29	203	180
30-34	165	142
35-39	118	91
40-44	55	41
45-49	15	5
TFR	4.0	3.4

Note: Age-specific fertility rates are per 1,000 women. CDHS 2000 rates pertain to the five-year period preceding the survey, CDHS 2005 pertain to the three-year period preceding the survey.

¹ NIS, DGH, and ORC Macro, 2001

Figure 5.1 Trends in Fertility

5.3 CHILDREN EVER BORN AND LIVING

Data on the number of children ever born reflect the accumulation of births over the past 30 years and therefore have limited relevance to current fertility levels, particularly when the country has experienced a decline in fertility. Nevertheless, information on children ever born (or parity) is useful in looking at how average family size varies across age groups and for looking at the level of primary infertility, the inability to bear children. Comparison of the differences in the mean number of children ever born and surviving reflects the cumulative effects of mortality levels during the period in which women have been bearing children.

Table 5.4 shows the percent distribution of all women and currently married women by the number of children ever born and the mean number of children ever born and mean number of children living. More than 9 out of 10 women age 15-19 (95 percent) have never given birth. However, this proportion declines quickly to 23 percent among women age 25-29 and to 9 percent or less among women age 35 and above. On average, Cambodian women have attained a parity of 5.3 children by the end of their reproductive years. This is 1.9 children more than the total fertility rate, a difference brought about by more recent dramatic declines in fertility.

The same pattern is replicated for currently married women, except that the mean number of children ever born is higher for currently married women (3.5 children) than for all women (2.3 children). The difference between all women and currently married women in the mean number of children ever born is due to the substantial proportion of young and unmarried women in the all-women category who exhibit lower fertility. It is evident that there is little extramarital childbearing: among all teenage women, only 5 percent have given birth to at least one child, while among currently married teenage women, 49 percent have begun childbearing. If rates of extramarital childbearing were high, then one would expect to see higher rates of childbearing among all teenage women.

Table 5.4 Children ever born and living

Total	7.1	15.6	18.5	16.5	13.4	10.4	6.9	4.5	3.1	1.9	2.1	100.0	10,087	3.45	3.01	

As would be expected, the mean number of children ever born and mean number of children surviving rise monotonically with increasing age of women. Comparison of the mean number of children ever born with the mean number of living children reveals the experience of child loss among Cambodian women. By the end of their reproductive years (age 45-49), married women in Cambodia have given birth, on average, to 3.5 children, with 3.0 surviving.

Voluntary childlessness is not common in Cambodia and currently married women with no children are likely to be those who are unable to bear children (primary infertility). While 51 percent of currently married adolescent women are childless, this proportion decreases to 6 percent among currently married women age 25-29, and continues to decline with increasing age. The percentage childless among currently married women at the end of the reproductive period (age 45-49) indicates that primary infertility among currently married women is low (2 percent).

5.4 BIRTH INTERVALS

Longer birth intervals contribute to improved health status of both mother and child (Rutstein, 2005). Infants born within two years of the birth of a previous child experience a higher risk of health problems. Table 5.5 shows the distribution of second and higher order births that occurred in the five years preceding the survey by the number of months since the previous birth, according to background characteristics.

In 2005, 18 percent of non-first births in Cambodia occurred less than 24 months after the preceding birth (compared with 21 percent in 2000), with 7 percent occurring less than 18 months after the preceding birth. Fifty-two percent of women give birth at least 36 months after the previous birth, an improvement over the comparable figure from the 2000 CDHS (45 percent). The overall median birth interval is 36.8 months. This means that half of the births in Cambodia occur within 36 months of the previous birth, and half occur after an interval of 36 months or longer. Data also indicate that birth intervals increase with increasing age of women. Twenty-five percent of births to women age 20-29 occurred within two years of the previous birth, compared with only 14 percent of births among women age 40 and above.

The median birth interval rises from 31.7 months among women age 20-29 to 44.5 months among women age 40 and above. Birth intervals do not vary much by birth order, sex of the preceding child, or urban-rural residence. However, the birth interval does vary markedly by the survival status of the preceding birth. More than four times as many births occurred within an 18-month interval when the preceding child had died than when the child was still alive. The median birth interval is 38.0 months if the previous child is living, but falls to 27.6 months if the preceding child is dead. Median birth intervals are shortest in Preah Vihear/Steung Treng (32.7) and Kampong Chhnang (32.9), and significantly longer in Phnom Penh and Kampong Cham (39.9) and Svay Rieng (39.7). Mothers with more education have longer birth intervals: those with no education have a median birth interval of 34.1 months, while those with secondary and higher levels of education have a median birth interval of 42.2 months. These results are consistent with the level of fertility: birth intervals are shorter when the TFR is high and longer when TFR is low.

Table 5.5 Birth intervals

Percent distribution of non-first births in the five years preceding the survey by number of months since preceding birth, and median number of months since preceding birth, according to background characteristics, Cambodia 2005

Total	7.3	10.9	29.6	19.4	7.7	4.3	20.9	100.0	5,638	36.8

Note: First-order births are excluded from this table. The interval for multiple births is the number of months since the preceding pregnancy that ended in a live birth. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.

5.5 AGE AT FIRST BIRTH

Early age at childbearing has a detrimental effect on the health of both mother and child. It also frequently leads to a longer reproductive span and higher level of fertility. Table 5.6 presents the median age at first birth and the percentage of women who first gave birth by specific exact ages, by five-year age groups.

The median age at first birth is 21.8 years for the youngest cohort (age 25-29) for whom a median could be computed and varies between 21.7 and 22.5 for the older cohorts, with no discernible pattern in variation.

Current age	Percentage who gave birth by exact age					Percentage who have never given birth	Number of women	Median age at first birth
	15	18	20	22	25			
15-19	0.2	na	na	na	na	94.8	3,601	a
20-24	0.4	8.9	26.3	na	na	51.5	3,045	a
25-29	0.6	12.2	29.9	51.5	69.6	23.3	2,051	21.8
30-34	0.9	8.5	29.5	53.3	73.4	11.0	2,082	21.7
35-39	0.4	6.8	23.4	44.2	70.6	9.3	2,229	22.5
40-44	0.2	8.9	31.6	52.0	72.1	8.7	2,112	21.8
45-49	0.6	6.1	21.0	47.5	75.2	7.2	1,703	22.2

na = Not applicable due to censoring
a = Omitted because less than 50 percent of women had a birth before reaching the beginning of the age group

Table 5.7 presents the median age at first birth by background characteristics and age at the time of the survey. The median age at first birth is higher in urban areas than in rural areas, with a difference of one year among women age 25-49. Kampong Chnang has the highest median age at first birth (23.3), while Mondol Kiri/Rattanak Kiri has the lowest median age at first birth (20.7). While there is a positive relationship between educational attainment and median age at first birth, there is only a difference when a woman has secondary or higher education. There is no difference in median age at first birth between women with no education and women with primary education. There is no clear pattern in median age at first birth by wealth quintile.

Table 5.7 Median age at first birth

Median age at first birth among women age 25-49, by current age, according to background characteristics, Cambodia 2005

5.6 TEENAGE PREGNANCY AND MOTHERHOOD

Teenage fertility is a major health concern because teenage mothers and their children are at high risk of illness and death. Childbearing during the teenage years can also have dire social consequences, curtailing the educational and employment opportunities of women. Early initiation into childbearing is also often associated with higher lifetime levels of fertility. Table 5.8 presents the proportion of women age 15-19 (teenagers) who are mothers or pregnant with their first child, by background characteristics.

Table 5.8 Teenage pregnancy and motherhood

Percentage of women age 15-19 who have had a live birth or who are pregnant with their first child, and percentage who have begun childbearing, by background characteristics, Cambodia 2005

Total	5.2	2.7	7.8	3,601

A small percentage of women age 15-19 have become mothers or are currently pregnant with their first child (8 percent). The percentage of women who have begun childbearing increases with age, from none among women age 15, to 23 percent among women age 19. Six percent of urban girls begin childbearing in their teens and 8 percent of rural girls have also begun their childbearing before the age of twenty. The level of teenage fertility is strongly associated with education. One in five teenagers who have never been to school have begun childbearing, compared with one in ten teenagers who have a primary school education, and fewer than one in 20 teenagers with secondary or higher education. In Cambodia, any education is associated with lower proportions of early childbearing. However, the proportion of women age 15-19 who have had no schooling is small (8 percent of all young women age 15-19). The percentage of teenagers who have begun childbearing is lowest in Takeo (4 percent) and highest in Mondol Kiri/Rattanak Kiri (22 percent).

In many countries in the developing world, there are very little data on the practice of abortion. It is illegal in a number of countries, often has negative social connotations, and is often considered against religious principles. The practice of abortion was legalized in Cambodia in 1997. According to the 1997 law, abortions can be conducted only by medical doctors, medical practitioners or midwives authorized by the Ministry of Public Health, and can only be carried out in a hospital, health center, health clinic or maternity ward. Abortions can only be legally conducted before the 12th week of pregnancy unless one of a number of specific conditions are met, which permit later abortions (Kram, legal decree, November 12, 1997 on abortion).

In order to better understand the practice of abortion in Cambodia, questions on the practice were integrated into the reproductive section of the CDHS questionnaire. The results present an estimation of the frequency of abortion over women's lifetime, and of the frequency of abortion in the past five years. Information was collected on the person who performed the abortion, the pregnancy duration, the place where the abortion took place, and the persons who assisted with the abortion. Pregnancy outside of marriage is not socially acceptable in Cambodia, thus it is likely that not all women who have had an abortion would be willing to report having done so. Thus, abortion statistics may likely be underestimates of the true level of abortion. Women age 15-49 account for one in five women of reproductive age. If there is significant under-reporting of abortions among women in this age group, it would affect the overall estimate of the abortion rate in the population.

6.1 NUMBER OF INDUCED ABORTIONS

Table 6.1 presents the percent distribution of all women age 15 to 49 by the number of induced abortions they have had over their lifetime, by background characteristics. In Cambodia, eight percent of women age 15 to 49 reported having had one or more abortions in their lifetime.

Women are more likely to resort to abortion as they get older. Less than one percent of women age 15 to 19 reported having had an abortion. Fifteen percent of women over age 34 have had at least one abortion. Abortion also increases as women have more living children. Less than one percent of women with no children reported ever having had an abortion. As many as one in five women with four children has had at least one abortion. The proportion declines somewhat among women with five, six, or more children, but remains above ten percent.

The practice of abortion varies by urban/rural residence. Urban women are more likely than rural women to have an abortion (11 percent compared with 7 percent). Urban women are also more likely to have more than one abortion. The percent of women who have relied on abortion varies across provinces. As many as 16 percent of women in Kampong Cham have had an abortion, and over 10 percent of women in Banteay Mean Chey, Battambang/Krong Pailin, and Phnom Penh have had abortions. On the other hand, only 2 and 3 percent of women in Mondol Kiri/Rattanak Kiri and Kampong Thom reported having had an abortion.

Figure 6.1 presents the distribution of women who report having at least one induced abortion according to the number of abortions they have had. While most women who have had an abortion have had only one, over 40 percent of women who have had an abortion have had more than one. One in four women who have had abortions report having had two abortions, and one in five women who have had abortions report having had three or more induced abortions. The percent of women who have multiple abortions among women who have had abortions has increased over the past five years, from 29 percent (2000 CDHS) to 44 percent (2005 CDHS).

Figure 6.1 Distribution of Number of Abortions for Women Who Report Having an Induced Abortion

CDHS 2005

6.2 ABORTION IN THE PAST FIVE YEARS

In order to obtain information on the recent practice of abortion and to avoid interviewing women about events in the distant past, which can be difficult to recall, detailed questions concerning abortion were asked only to those women who have had an abortion since 2000. In Table 6.2 and subsequent tables, education of the respondent has been grouped into two categories: no education and primary education or higher, due to the relatively small number of cases.

Pregnancy duration at the time of abortion

Table 6.2 shows the percentage of women who reported having an abortion in the past five years and the distribution of those women by their pregnancy duration at the time of abortion. Overall, 4 percent of women had an abortion in the five years preceding the survey. The majority of these women aborted their pregnancy between the second and fourth month of pregnancy, four in ten had the abortion during the first two months of pregnancy, and 3 percent had the abortion after the fourth month of pregnancy.

Women with three or four living children are more likely than other women to have had an abortion, over half of whom had the abortion between the second and fourth month of pregnancy. Two-thirds of women with five or more living children had their abortion between the second and fourth month of pregnancy. Urban women are more likely than rural women to have had their abortions within the first two months of pregnancy, while the majority of rural women had their abortions between the second and fourth month of pregnancy. While the percentage of women who recently had an abortion does not vary by education, the duration of pregnancy at the time of abortion does differ. Women with some education are more likely than women with no education to have had their abortion within the first two months of pregnancy (44 versus 24 percent, respectively). The majority of women with no education had their abortion between the second and fourth month of pregnancy (71 percent).

Table 6.2 Pregnancy duration at the time of abortion

Percentage of women who had at least one induced abortion in the past five years and percent distribution of the last abortion during the past five years by pregnancy duration at the time of abortion, according to background characteristics, Cambodia 2005

Background characteristic	Percentage with at least one abortion in the past 5 years	Number of women	Pregnancy duration at the time of last abortion			Number of women with abortion in the past 5 years
			<2 months	2-4 months	5+ months

Total	3.5	16,823	39.9	56.8	3.3	582

Place of abortion

Women who had an abortion in the past five years were asked where the most recent abortion took place (Table 6.3). Forty-eight percent of women had their abortions in a health facility, 11 percent in a public facility and 37 percent in a private facility. About the same proportion (45 percent) of abortions took place at home, 12 percent in the respondent's home and 33 percent in someone else's home. These figures show that abortions are as likely to have taken place in a health facility as at home. A higher percentage of urban women had their abortions within a health facility (58 percent) than did rural women (45 percent).

Table 6.3 Place of abortion

Percent distribution of the last abortion during the past five years by place of abortion, according to background characteristics, Cambodia 2005

Background characteristic	Place of abortion					Total	Number of women with abortion in the past 5 years
	Public health facility	Private health facility	Respondent home	Other home	Other/missing

Note: An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed

Persons who helped with the abortion

Women who had an abortion in the past five years were asked to identify the type of person or persons who assisted with their last abortion. If more than one person attended to the abortion, only the most qualified person is presented in Table 6.4. Four in five women received help from a doctor, nurse, midwife, or other health worker. Seven percent of women received help from a traditional birth attendant or Kru Khmer, and 8 percent did not receive help from anyone. There are no differentials in assistance at abortion by the woman's age. However, there are variations by pregnancy duration. Women who had their abortion in the first two months of pregnancy are more likely than women who had the abortion at a later stage of pregnancy to have no assistance (11 percent compared with 6 percent). Urban women are more likely to have help from a health professional (87 percent) compared with rural women (76 percent). On the other hand, while 8 percent of rural women received help from a traditional birth attendant and 8 percent from a relative or friend, the corresponding proportion for urban woman is 2 percent and 3 percent, respectively.

Background characteristic	Persons who helped the last abortion					Total	Number of women with abortion in the past 5 years
	Doctor/nurse/ midwife/ other health worker	Traditional birth attendant/ Kru Khmer	Relative/ friend/ other	No one	Missing

This chapter presents information from the 2005 CDHS on contraceptive knowledge, attitudes and behaviour. Comparisons are also made, where appropriate, with findings from the 2000 CDHS to evaluate changes over the past five years.

7.1 KNOWLEDGE OF CONTRACEPTIVE METHODS

Acquiring knowledge about family planning is an important step towards gaining access to and using a suitable contraceptive method in a timely and effective manner. Individuals who have adequate information about the available methods of contraception are better able to make choices about planning their families. Thus, one of the main objectives of the 2005 CDHS was to assess the level of knowledge of family planning methods among women of reproductive age. Data on knowledge of contraception was collected in two ways. First, respondents were asked to mention all the methods of contraception that they had heard of spontaneously. For methods not mentioned spontaneously, the interviewer described the method and probed for whether the respondent recognized it. Prompted and unprompted knowledge are combined in this report.

Information was collected for 11 modern contraceptive methods: female and male sterilization, daily pills, monthly pills, IUD, injectables, implants, male condoms, female condoms, lactational amenorrhoea method (LAM), and emergency contraception. Information was also collected on two traditional methods (periodic abstinence and withdrawal). In addition, provision was made in the questionnaire to record any other method named spontaneously by the respondents.

Table 7.1 shows knowledge of contraception among all women and currently married women age 15-49. Knowledge of contraceptive methods is high with 99 percent of all women and 99 percent of currently married women knowing at least one modern method of contraception. Knowledge of traditional methods is lower. Forty-eight percent of all women and 62 percent of currently married women know at least one traditional method. Daily pills are the most widely known method (97 percent of all women and 98 percent of currently married women), followed closely by male condoms (95 percent of all women and 96 percent of currently married women) and injectables (93 percent of all women and 97 percent of currently married women).

Table 7.1 Knowledge of contraceptive methods

Percentage of all women and currently married women who know any contraceptive method, by specific method, Cambodia 2005

Method	All women	Currently married women
Any method	98.6	99.4
Any modern method	98.6	99.3
Female sterilization	68.1	76.6
Male sterilization	46.5	53.4
Daily pill	96.8	98.2
Monthly pill	57.6	65.3
IUD	84.4	90.7
Injectables	93.1	96.9
Implants	68.5	76.2
Male condom	95.1	96.4
Female condom	18.8	18.9
Lactational amenorrhoea (LAM)	29.4	35.0
Emergency contraception	4.9	5.4
Any traditional method	47.5	61.5
Rhythm	31.9	39.5
Withdrawal	35.4	49.2
Folk method	0.5	0.7
Mean number of methods known	7.3	8.0
Number of women	16,823	10,087

The mean number of methods known, a rough indicator of the breadth of knowledge of family planning methods, is high in Cambodia. Breadth of contraceptive knowledge is slightly higher among currently married women (eight methods) than all women (seven methods).

With almost all currently married women knowing at least one method of contraception, there is very little variation in knowledge by background characteristics (Table 7.2). Knowledge of any method of contraception is notably lower in Mondol Kiri/Rattanak Kiri, where only three-quarters of women have ever heard of any method or any modern method of contraception.

¹ Female sterilization, male sterilization, daily pill, monthly pill, IUD, injectables, implants, male condom, female condom, lactational amenorrhea method (LAM), and emergency contraception

Overall, knowledge of contraception has risen in the past five years. Knowledge of any method of contraception among all women has increased from 92 percent in 2000 to 99 percent in 2005. Some of the greatest increases in knowledge were shown in female condoms and LAM. Knowledge of female condoms increased from five percent to 19 percent among all women and currently married women, and knowledge of LAM increased from seven percent to 29 percent among all women and from nine percent to 35 percent among currently married women. Knowledge of any traditional method increased as well. On the other hand, knowledge of the monthly pill decreased from 71 percent to 58 percent among all women and from 77 percent to 65 percent among currently married women.

7.2 EVER USE OF CONTRACEPTIVE METHODS

All women interviewed in the 2005 CDHS who said that they had heard of a method of family planning were asked whether they had ever used that method. Table 7.3 shows the percentage of all women and currently married women who have ever used specific methods of family planning, by age.

LAM = Lactational amenorrhea method

Six in ten currently married women have used a contraceptive method: 53 percent have used a modern method, and 26 percent have used a traditional method. The methods most commonly used by married women are daily pills (31 percent), injectables (24 percent), withdrawal (19 percent), and periodic abstinence (12 percent).

Ever use of contraception increases steadily with age until the late thirties, after which ever use of contraception gradually declines. Among currently married women, ever use of any method rises from 30 percent among women age 15-19 to 73 percent among women age 35-39.

7.3 CURRENT USE OF CONTRACEPTIVE METHODS

The level of current use of contraceptive methods is one of the indicators most frequently used to assess the success of family planning program activities. It is also widely used as a measure in analysing the determinants of fertility. This section focuses on the levels and differentials in current use of family planning in Cambodia.

Current contraceptive use among all women and currently married women is presented in Table 7.4 by age group. Forty percent of married women are currently using a method of family planning. This includes 27 percent who are using a modern method and 13 percent who are using a traditional method. The most widely used method is the daily pill (11 percent) followed by withdrawal (8 percent) and injectables (8 percent).

Note: If more than one method is used, only the most effective method is considered in this tabulation.
LAM = Lactational amenorrhea method

As shown in Table 7.5, there are marked differences in the contraceptive prevalence rate among women by background characteristics. Looking at the data for currently married women, urban women are more likely than rural women to be using any method of contraception (49 percent versus 38 percent). Urban women are more likely to use both modern and traditional methods than rural woman. However, rural women use injectables in greater proportion than urban women (9 percent versus 4 percent). There is also substantial variation in current use by province. Current use among married women is highest in Phnom Penh (58 percent) and lowest in the Mondol Kiri/Rattanak Kiri (22 percent).

Middle	11.5	2.5	8.9	0.1	61.3	100.0	1,952
Fourth	12.6	4.0	8.6	0.0	58.7	100.0	2,037
Highest	21.7	10.6	11.1	0.1	46.0	100.0	2,112
Total	12.8	4.5	8.3	0.1	60.0	100.0	10,087

Note: If more than one method is used, only the most effective method is considered in this tabulation.
LAM = Lactational amenorrhea method

Contraceptive use is associated with the number of living children a woman has; it is highest among women with three to four children (48 percent) and lowest among women with no children (seven percent). Current contraceptive use increases with educational attainment and wealth quintile. Thirty percent of married women with no education are currently using contraception compared with 50 percent of married women with secondary and higher levels of education. Use of contraception rises steadily with rising wealth quintile, the percentage of currently married women using contraception ranges from 31 percent in the lowest wealth quintile to 54 percent in the highest wealth quintile.

Since the 2000 CDHS, the proportion of currently married women who are using any method of contraception has increased significantly, from 24 percent to 40 percent. The proportion of currently married women using any modern method has increased from 19 percent to 27 percent while the proportion using any traditional method has increased from five percent to 13 percent. It should be noted that while the classification of LAM switched from a traditional method in the 2000 CDHS to a modern method in the 2005 CDHS, the current use of LAM was less than one percent in both surveys and therefore does not affect the overall trend in use of modern and traditional methods. By individual

methods, the largest increases have been achieved among currently married women using daily pills (5 percent in 2000 to 11 percent in 2005) and withdrawal (2 percent to 8 percent).

7.4 NUMBER OF CHILDREN AT FIRST USE OF CONTRACEPTION

Family planning may be used to either limit family size or delay the next birth. Couples using family planning to limit family size adopt contraception when they have already had the number of children they want. When contraception is used to space births, couples may start using family planning earlier, with the intention of delaying a possible pregnancy. This may be done even before a couple has had their desired number of children.

Women interviewed in the 2005 CDHS were asked how many children they had at the time they first used a contraceptive method. Table 7.6 shows the percent distribution of women by the number of living children at the time of first use of contraception, according to current age.

Current age	Never used	Number of living children at time of first use of contraception					Total	Number of women
		0	1	2	3	4+		
15-19	96.8	1.4	1.6	0.1	0.0	0.0	100.0	3,601
20-24	68.5	6.5	17.6	6.5	0.8	0.1	100.0	3,045
25-29	45.8	4.5	22.0	18.7	6.7	2.3	100.0	2,051
30-34	37.2	2.6	15.1	18.2	14.4	12.5	100.0	2,082
35-39	36.9	1.5	8.6	14.5	16.1	22.4	100.0	2,229
40-44	44.0	0.6	4.4	6.7	9.0	35.3	100.0	2,112
45-49	57.7	0.5	3.6	4.1	4.6	29.4	100.0	1,703
Total	59.6	2.7	10.1	8.9	6.5	12.2	100.0	16,823

The data show that 12 percent of women first used contraception when they had four or more children. Only 3 percent of women first used contraception before having any children. Ten percent of women began to use contraception after having their first child.

The age pattern of first use of contraception shows that younger women are more likely to start using contraception at lower parities than older women. For example, roughly one in five women age 25-29 started to use contraception after the birth of her first child, compared with less than one in ten women age 35-39.

7.5 USE OF SOCIAL MARKETING BRANDS

Current users of daily pills and condoms were asked for the brand name of the pills and condoms they last used. This information is useful in monitoring the success of social marketing programmes that promote a specific brand.

The socially marketed contraceptive brands are prevalent in Cambodia. Just under half of daily pill users (49 percent) use “OK” brand pills while around two-thirds of condom users use “#1” brand condoms (Table 7.7). The proportion of pill users who use OK pills increases with wealth quintile from 41 percent in the two lowest wealth quintiles to 75 percent in the highest wealth quintile.

Table 7.7 Use of social marketing brand pills and condoms

Percentage of pill and condom users using a specific social marketing brand, by background characteristics, Cambodia 2005

Background characteristic	Percentage of pill users using "OK" pill	Number of women using the daily pill	Percentage of condom users using "# 1"	Number of women using condoms

Note: Table excludes pill and condom users who do not know the brand name. Condom use is based on women's reports. Figures in parentheses are based on 25-49 unweighted cases. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.

7.6 KNOWLEDGE OF FERTILE PERIOD

The successful use of natural family planning methods depends largely on an understanding of when during the menstrual cycle a woman is most likely to conceive. All women in the survey were asked about their knowledge of the fertile period. Specifically, they were asked whether there are certain days between two menstrual periods when a woman is more likely to become pregnant if she has sexual intercourse. Those who said yes were further asked if this time is just before the period begins, during the period, right after the period ends, or halfway between the two periods.

Table 7.8 shows that almost three-quarters of women do not know when a woman's fertile period is, and only 13 percent correctly state that the fertile time in a women's menstrual cycle is halfway between two periods. Knowledge of the fertile period is much higher among women who are users of rhythm method. Almost three in four women (73 percent) possess accurate knowledge of the timing of the fertile period. However, 13 percent of users of rhythm method report they don't know when the fertile period is, and an additional 11 percent believe it is right after a woman's period has ended. Thus, one in four users of rhythm method are at risk for unwanted pregnancy.

Perceived fertile period	Users of rhythm method	Nonusers of rhythm method	All women
Just before her period begins	1.5	1.0	1.0
During her period	0.8	0.7	0.7
Right after her period has ended	10.6	5.4	5.5
Halfway between two periods	73.0	11.7	13.4
Other	0.3	0.1	0.1
No specific time	0.4	5.0	4.9
Don't know	13.4	76.1	74.4
Missing	0.0	0.1	0.1
Total	100.0	100.0	100.0
Number of women	453	16,370	16,823

7.7 TIMING OF STERILIZATION

While only 1 percent of women of reproductive age are relying on sterilization as their method of contraception, Table 7.9 shows the distribution of sterilized women by age at the time of their sterilization. Almost seven in ten women who have been sterilized received the operation before the age of 35. It was most common for women who had been sterilized to have received the sterilization from the ages of 30 to 34 (33 percent). Twenty-seven percent of women who had received a sterilization were sterilized from age 25 to 29. The median age at sterilization has varied between 32 and 33 years showing no strong trend over time.

Years since operation	Age at time of sterilization						Total	Number of women	Median age ¹
	<25	25-29	30-34	35-39	40-44	45-49			
<2	(6.6)	(17.6)	(32.7)	(16.4)	(19.2)	(7.4)	100.0	58	32.5
2-3	*	*	*	*	*	*	100.0	18	31.7
4-5	(9.2)	(24.5)	(30.5)	(16.0)	(19.8)	(0.0)	100.0	20	32.0
6-7	*	*	*	*	*	*	100.0	20	33.4
8-9	*	*	*	*	*	*	100.0	16	32.4
10+	(11.3)	(43.6)	(37.2)	(7.8)	(0.0)	(0.0)	100.0	49	a
Total	9.0	27.2	33.1	16.5	11.9	2.4	100.0	180	31.4

Note: Figures in parentheses are based on 25-49 unweighted cases. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.

¹ Median ages are calculated only for women sterilized at less than 40 years of age to avoid problems of censoring.

a = Not calculated due to censoring

7.8 SOURCE OF FAMILY PLANNING METHODS

Information on sources of modern contraceptives is useful for family planning managers and service providers. Women who reported using a modern method of contraception at the time of the survey were asked where they obtained the method the last time and interviewers recorded the name and location of the source. To ensure accuracy in reporting, supervisors and editors verified the type of source from the written response.

Table 7.10 shows that twice as many contraceptive users obtain methods from the public sector than the private medical sector (40 percent compared with 20 percent). Thirty percent of all contraceptive users obtain their methods from public health centers, and one in five women who use contraception obtain their methods from a shop.

Most recent source of method	Female sterilization	Male sterilization	Daily pill	Monthly pill	IUD	Injectables	Implants	Male condom	Total
Public sector	78.4	*	32.4	5.7	34.9	57.9	*	20.6	40.2

Note: An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.
¹ Total includes other modern methods but excludes lactational amenorrhea method (LAM).
 PP = Phnom Penh
 RH = Referral hospital

There is notable variation in source of method by type of contraceptive. Women who use the monthly pill or condoms most often obtain these method from a shop (64 percent of monthly pill users and 47 percent of condom users). Shops are an important source for users of the daily pill as well (31 percent of users); however, users of daily pills also commonly obtain their method from the public sector (32 percent of users), mainly health centers. The private medical sector is the largest source for IUDs. Over half of women who use an IUD obtained it from the private medical sector while 35 percent obtained their IUD from a public sector source. Finally, the public sector is the most common source of contraception among women who use injectables (58 percent of injectable users).

Since the 2000 CDHS there have been some slight changes in the sources for contraceptive methods. Users of monthly pills are now less likely to obtain them from the public sector and more likely to obtain them from “other” sources, and the private medical sector has replaced the public sector as the predominant source for IUD.

7.9 COST OF FAMILY PLANNING METHODS

In the 2005 CDHS, users of contraception were asked how much they paid the last time they obtained the method, including the cost of the method itself and any consultation. Table 7.11 presents the findings separately for the public and private sector as well as for all sources together. Overall, 6 percent of users reported obtaining their method for free, which includes one-quarter of sterilized women, 14 percent of women with IUDs, and 15 percent of women using condoms with their partners getting their method for free. Among users who pay for their method, the median cost is about 1,000 riels, or 24 cents. That is, about half of women pay more and half of women pay less than 1,000 riel (24 cents) for their method.

Table 7.11 Cost of modern contraceptive methods

Percentage of current users of contraception who did not pay for the method and who do not know the cost of the method and the median cost of the method by source of current method, according to current method, Cambodia 2005

Source of method/cost	Female sterilization	Male sterilization	Daily pill	Monthly pill	IUD	Injectables	Implants	Male condom	Total

Number of women	180	9	1,116	159	178	794	19	294	2,749

Note: Table excludes lactational amenorrhea method (LAM). Costs are based on the last time current users obtained the method. Costs include consultation costs, if any. For condom, costs are per package; for pills, per cycle. For sterilization, data are based on women who received the operation in the 5 years before the survey. Figures in parentheses are based on 25-49 unweighted cases. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.

¹ Median cost is based only on those women who reported a cost.

USD = United States of America dollar

7.10 INFORMED CHOICE

Current users of modern methods who are well informed about the side effects and problems associated with methods and who know of a range of method options are in a better position to make an informed choice about the method they would like to use. Current users of various modern contraceptive methods were asked whether, at the time they were adopting a particular method, they were informed about the possible side effects or problems they might have with the method and what to do if they experienced side effects. Women who were sterilized in the five years preceding the survey were asked whether they were informed that sterilization is permanent. Table 7.12 shows the percentage of current users of modern methods who were informed about the side effects or problems with the method used, informed about what to do if they experienced side effects, and informed of other methods they could use, according to the type of method they are currently using and initial source of the method. In addition, the table shows the percent of sterilized women who were told the sterilization was permanent.

Table 7.12 Informed choice

Among current users of modern contraceptive methods who started the last episode of use within the five years preceding the survey, the percentage who were informed about possible side effects or problems of that method, the percentage who were informed about what to do if they experienced side effects or problems, and the percentage who were informed about other methods they could use, by method and initial source; and among sterilized women, the percentage who were informed that the method is permanent, by source of method, Cambodia 2005

Method/source/ background characteristic	Percentage who were informed about side effects or problems of method used	Percentage who were informed about what to do if side effects experienced	Percentage who were informed by a health or family planning worker of other methods that could be used	Number of women	Among sterilized women, percentage who were informed that sterilization is permanent ¹	Number of sterilized women

Note: Table excludes users who obtained their method from friends/relatives.

¹ Among women who were sterilized in the five years preceding the survey

² Source at start of current episode of use

na = Not applicable

PP = Phnom Penh

RH = Referral hospital

Overall, 63 percent of contraceptive users were informed about side effects of their method when they started their current episode of using that method. Six in ten women were informed about what to do if they experienced side effects, and 55 percent were informed by a health or family planning worker about other methods they could use. Thirteen percent of women who were sterilized in the five years preceding the survey said they were not told the sterilization would be permanent.

Findings on informed choice vary by method. Users of implants are most likely to have received all three pieces of information relating to informed choice. Only 31 percent users of the monthly pill were informed of side effects, and 29 percent were told about what to do in the event of side effects. The lowest proportion of women who were informed of other methods occurs among users of female sterilization (32 percent).

7.11 FUTURE USE OF CONTRACEPTION

Intention to use a method of contraception is an important indicator of the potential demand for family planning services. Currently married women who were not using contraception at the time of the survey were asked about their intention to use family planning methods in the future. The results are presented in Table 7.13.

Intention to use in the future	Number of living children ¹					Total
	0	1	2	3	4+	
Intends to use	51.2	67.1	63.9	52.6	36.1	51.6
Unsure	6.8	4.8	4.2	5.4	3.0	4.2
Does not intend to use	42.0	28.1	31.8	41.8	60.9	44.1
Missing	0.0	0.1	0.1	0.1	0.1	0.1
Total	100.0	100.0	100.0	100.0	100.0	100.0
Number of women	415	1,220	1,193	1,010	2,214	6,052

¹ Includes current pregnancy

More than half (52 percent) of currently married women who were not using any contraception at the time of the survey say that they intend to use a family planning method some time in the future. Forty-four percent do not intend to use any method, while 4 percent are unsure of their intention. The proportion of women who intend to use in the future varies by the number of living children, increasing from 51 percent for those with no living children to a peak at 67 percent among those with one child. These women are likely interested in spacing subsequent births. Over the past five years, there has been an increase in the proportion of married women not using at the time of the survey but who intend to use in the future (from 42 percent in 2000 to 52 percent in 2005).

7.12 REASONS FOR NOT INTENDING TO USE A CONTRACEPTIVE METHOD IN THE FUTURE

An understanding of the reasons why people do not use family planning methods is critical in designing programmes that are effective in reaching women with unmet need and to improve the quality of family planning services. Table 7.14 shows currently married nonusers who do not intend to use a contraceptive method in the future by the main reasons for not intending to use family planning. Around 47 percent cited fertility-related reasons for not intending to use contraception. In particular, 20 percent said that the main reason for not intending to use was a belief that they had low fertility or could not get pregnant. In addition, 36 percent of married women not using a contraceptive cited health concerns as their main reason for having no intention to use a method.

Table 7.14 Reason for not intending to use contraception in the future

Percent distribution of currently married women who are not using contraception and who do not intend to use in the future by main reason for not intending to use, Cambodia 2005

Reason	Percent
Fertility-related reasons	46.6
Infrequent sex/no sex	9.4
Menopausal/had hysterectomy	7.3
Subfecund/infecund	20.1
Wants as many children as possible	9.7
Opposition to use	2.0
Respondent opposed	1.2
Husband/partner opposed	0.6
Others opposed	0.2
Religious prohibition	0.1
Lack of knowledge	0.7
Knows no method	0.5
Knows no source	0.2
Method-related reasons	42.1
Health concerns	35.8
Fear of side effects	4.0
Lack of access/too far	0.0
Costs too much	0.5
Inconvenient to use	0.5
Interfere with body's normal processes	1.3
Other	7.6
Don't know	1.0
Total	100.0
Number of women	2,667

The proportion of women who gave opposition to family planning as their reason for not using contraception dropped from 9 percent in the 2000 CDHS to 1 percent in this survey. Wanting more children was given as the reason for non-use by equal proportions of women in 2000 and 2005 (10 percent). The proportion of women who cited health concerns increased from 26 percent in 2000 to 36 percent in 2005.

7.13 PREFERRED METHOD OF CONTRACEPTION FOR FUTURE USE

Demand for specific methods can be assessed by asking nonusers which methods they intend to use in the future. Table 7.15 presents information on method preference among currently married women who are not using a contraceptive method but say they intend to use in the future. Thirty-five percent of married women who intend to use a contraceptive but were not using at the time of the survey say the method they intend to use is the daily pill. One in four women intend to use injectables, and 14 percent are unsure which method they intend to use.

Daily pill and injectables were also the most preferred methods for future use in the 2000 CDHS. However, the proportion of women intending to use daily pill has increased from 26 percent in 2000 to 35 percent in 2005, while the proportion intending to use injectables has decreased from 34 percent to 25 percent.

7.14 EXPOSURE TO FAMILY PLANNING MESSAGES

The media can be a major source of family planning messages. Information about public exposure to messages on a particular type of media allows policymakers to ensure the use of the most effective means of communication for various target groups in the population. To assess the effectiveness of electronic and print sources on the dissemination of family planning information, respondents in the 2005 CDHS were asked if they had heard or seen family planning messages on the radio or television, or read a family planning message in a newspaper or magazine in the months leading up to the survey. The results are shown in Table 7.16.

Media messages about family planning information are largely accessed through television and radio with lesser access through the print media. For example, 67 percent of women had recently heard about family planning on television and 58 percent had recently heard about family planning on the radio. By contrast, only 15 percent of women got such information from newspapers or magazines. Almost one-quarter of women were not exposed to a family planning message on any of these three media in the months preceding the survey.

Significant variation is observed in exposure to family planning messages by background characteristics. Younger women are more likely to be exposed to family planning messages than older women, and women in rural areas have less exposure to essential information on health and family planning through the media than women in urban areas. For example, rural women are more than twice as likely as urban women not to have seen or heard family planning messages in any of the three types of media (27 percent versus 12 percent). Educational attainment and wealth quintile are both associated with improved access to family planning messages in the media. For example, only 11 percent of women with primary education were exposed to a family planning message in a newspaper or magazine, compared with 36 percent of women with secondary and higher education. In addition, the proportion of women exposed to family planning messages on television increases steadily from 42 percent among women in the lowest wealth quintile to 88 percent among those in the highest wealth quintile.

Method	Percent

Education					
No schooling	43.7	51.3	2.6	37.3	3,270
Primary	56.2	65.1	10.8	25.5	9,389
Secondary and higher	71.7	83.7	35.6	10.4	4,165
Wealth quintile					
Lowest	43.1	42.3	4.0	44.3	3,017
Second	51.5	55.7	6.2	31.7	3,164
Middle	57.0	67.2	9.4	23.2	3,245
Fourth	64.5	74.4	15.9	18.1	3,308
Highest	67.8	87.9	35.1	8.7	4,089
Total	57.6	67.0	15.4	24.0	16,823

Exposure to family planning messages through the media is highest in Phnom Penh, Kandal, and Battambang/Krong Pailin. Less than half of women were exposed to a family planning message through any of the three types of media in Kampong Cham, Preah Vihear/Steung Treng, and Mondol Kiri/Rattanak Kiri.

7.15 CONTACT OF NONUSERS WITH FAMILY PLANNING PROVIDERS

Given the importance of family planning services to the improvement of mothers' and children's health, it is critical that every opportunity to meet a woman's family planning needs be fully exploited. In reality, however, health care providers miss these opportunities. Information on missed opportunities was gathered by asking women if they had visited a health facility in the 12 months preceding the survey. Those who visited a health facility were asked whether anyone at the facility had discussed family planning with them during any of their visits. Women were also asked

whether they had been visited by a fieldworker who talked with them about family planning in the 12 months preceding the survey.

The results of these questions for the group of women not using a method of contraception at the time of the survey are presented in Table 7.17. Three-quarters of nonusers did not have any contact with healthcare providers or fieldworkers with whom family planning was discussed. Around one in five nonusers (19 percent) reported being visited by fieldworkers who discussed family planning issues. Twenty-seven percent of nonusers visited a health facility during the 12 months preceding the survey; however, the majority of these women did not discuss family planning with any healthcare provider.

Background characteristic	Women who were visited by fieldworker who discussed family planning	Women who visited a health facility		Women who did not discuss family planning with a field - worker or at a health facility	Number of women
		Discussed family planning	Did not discuss family planning

7.16 HUSBAND'S KNOWLEDGE OF WIFE'S USE OF CONTRACEPTION

Concealment of use of contraception is an indication of absence of communication or disagreement on use of family planning. To shed light on the extent of communication on the use of contraception among married couples, married women who were using contraception at the time of the survey were asked whether their husband knew of their use. Almost all users (99 percent) reported that their husbands know about their use of contraception (Table 7.18). There is essentially no variation from universal husband's awareness of contraceptive use by their spouse by background characteristics.

¹ Includes women who report use of male sterilization or male condoms

This chapter examines the principal factors, other than contraception, that affect a woman's chances of becoming pregnant. These factors include marriage (including consensual unions), postpartum amenorrhea, abstinence from sexual relations, and termination of exposure to pregnancy. Marriage and sexual relations relate to childbearing; postpartum amenorrhea and abstinence affect the intervals between births; and menopause marks the end of childbearing. This chapter, will also take an in-depth look at more direct measures of the timing and level of exposure to the risk of pregnancy: the age at first sexual intercourse and the frequency of intercourse. Marriage is an important fertility indicator because, for most women in Cambodia it marks the beginning of regular exposure to the risk of pregnancy. Populations in which the age at first marriage is low also tend to experience early childbearing and high fertility. Measures of the onset of menopause are important since the probability of becoming pregnant decreases as women approach the end of their reproductive years and increasing proportions become infecund. Collectively, the above-mentioned factors determine the duration and pace of reproductive activity and hence are important in understanding fertility.

8.1 MARITAL STATUS

Table 8.1 shows the distribution of all women and men age 15-49 by current marital status. The data broadly indicate that 32 percent of Cambodian women of reproductive age have never been married, and 60 percent are currently married or cohabiting as if married. Divorced and separated women constitute 4 percent of women of reproductive age, and 4 percent are widows. A higher proportion of men age 15-49 have never been married (39 percent). However, this is partly a function of age distribution. Fewer men in the youngest age groups have ever been married compared with women in the same age groups. There are almost no men in the two oldest age groups that have never been married.

Age	Marital status						Total	Number of respondents
	Never married	Married	Living together	Divorced	Separated	Widowed		
WOMEN								
15-19	89.2	9.8	0.3	0.4	0.2	0.2	100.0	3,601

30-34	3.1	93.2	0.0	1.4	1.1	1.1	100.0	811
35-39	2.5	95.4	0.4	1.0	0.1	0.7	100.0	858
40-44	0.7	97.5	0.1	0.4	0.1	1.2	100.0	793
45-49	0.0	97.3	0.1	1.2	0.3	1.1	100.0	555
Total 15-49	38.7	58.8	0.2	0.8	0.9	0.6	100.0	6,731

Table 8.1 also shows that the proportion of women who have never married predictably decreases with age to a low of 4 percent among those age 45-49. This reflects the near-universality of marriage in Cambodian society. Consequently, the proportion of currently married women increases with age up to ages 30-39 (83 percent) and declines thereafter due to increasing levels of widowhood. The data on men reflect no relationship between age and widowhood; however, it is likely that this is due to men's greater propensity to remarry after having been widowed.

8.2 AGE AT FIRST MARRIAGE

In many societies, age at first marriage marks the point in a woman's life when childbearing becomes socially acceptable. Women who marry early will on average have a longer exposure to the risk of pregnancy. Therefore, early age at first marriage would imply early age at childbearing and a higher level of fertility for the society. Information on age at first marriage was obtained by asking all ever-married respondents the month and year they started living together with their first spouse, or if they could not remember the month and year, the age at which they started living with their first spouse. This information is presented in Table 8.2.

Note: Age at first marriage is the age at which the respondent began living with her/his first spouse/partner
na = Not applicable due to censoring
a = Omitted because less than 50 percent of the women or men began living with their husbands, wives or partners for the first time before reaching the beginning of the age group

The median age at first marriage among women in Cambodia has remained stable over the last two decades, at about 20 years of age. Men have a slightly older median age at first marriage of about 22 years. The proportion of women married by the age of 15 years has declined in the very recent past, dropping from 5 percent among women age 25-29 to 1 percent among women age 15-19. About half of Cambodian women are married by age 20, and 81 percent are married by age 25. Less than 1 percent of all Cambodian men were married before the age of 15, and only 10 percent were

married by age 18. This finding contrasts fairly sharply with the proportion of women married by age 18 (25 percent).

Table 8.3.1 shows the median age at first marriage among women age 25-49 by current age and selected background characteristics. Table 8.3.2 shows the median age at first marriage among men age 25-49. The median age at first marriage of urban women (20.7) is only slightly older than that of rural women (20.0). Men demonstrate greater urban/rural differences in median age at marriage than do women (23.9 years and 21.7 years, for urban and rural men, respectively). Median age at first marriage varies by 2.5 years across provinces, ranging from 18.6 in Mondol Kiri/Rattanak Kiri to 21.1 in Kampong Chhnang. Men's median age at first marriage varies by 3.6 years across provinces, where it is youngest in Svay Rieng (20.7) and oldest in Phnom Penh (24.3). One consistent pattern of difference in age at first marriage among Cambodian women of all ages is with regard to education. Women who have attained a high school education or higher marry on the average one year later than their less-educated countrywomen. Men with a high school education or higher marry on average 2 years later than their less-educated counterparts. For women there is no difference in median age at marriage by wealth quintile; however, men in the two highest quintiles have progressively older median ages at first marriage.

Note: Age at first marriage is the age at which the respondent began living with his first spouse/partner. Figures in parentheses are based on 25-49 unweighted cases. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.
a = Omitted because less than 50 percent of the men began living with their wives/partners for the first time before reaching the beginning of the age group

8.3 AGE AT FIRST SEXUAL INTERCOURSE

Age at first marriage is commonly used as a proxy for the onset of women's exposure to sexual intercourse and risk of pregnancy and sexually transmitted disease. However, since some men and women are sexually active before marriage, it is also important to measure the impact of age at first sexual intercourse on fertility. The 2005 CDHS asked women and men how old they were when they first engaged in sexual intercourse. The results are presented in Table 8.4 and Tables 8.5.1 and 8.5.2.

If one compares the percentage of women who had first sexual intercourse by exact ages 15-25 (Table 8.4) with the percentage of women first married by exact ages 15-25 (Table 8.2), one finds very little variation, indicating that women rarely engage in sexual activity prior to marriage. The percent of women age 25-49 never having had intercourse is 9 percent. The median age at first intercourse is slightly older than the median age at first marriage: 20.4 years, compared with 20.1 years, respectively.

Current age	Percentage who had first sexual intercourse by exact age:					Percentage who never had intercourse	Number of respondents	Median age at first intercourse
	15	18	20	22	25

na = Not applicable due to censoring
a = Omitted because less than 50 percent of the women/men had intercourse for the first time before reaching the beginning of the age group

Comparing the percentage of men who had first sexual intercourse by exact ages 15-25 (Table 8.4) with the percentage of men first married by exact ages 15-25 (Table 8.2), one again finds only small variations, indicating that men also do not typically engage in sexual activity prior to marriage. However, the percent of men age 25-29 never having had intercourse is 3 percent, about half the proportion of men who never married (6 percent). Among men, the median age at first intercourse is slightly younger than the median age at first marriage: 21.5 years of age, as compared with 22.1 years of age, respectively.

Table 8.5.1 shows differentials in the median age at first sexual intercourse by background characteristics for women, and Table 8.5.2 shows those differentials for men. For women (Table 8.5.1), the lack of pattern seen in the differentials for age at first marriage is repeated here for age at first sex, with no meaningful variation by age, little variation by region, and a one-year difference in the median age at first sexual intercourse between urban and rural residents (21.1 and 20.3 years, respectively). There is also a one-year difference between those who have secondary or higher education (21.4 years) and those who have less education (20.2-20.3 years). There are no differences in age at first marriage by wealth quintile. For men (Table 8.5.2), the same one-year difference in the

median age at first sexual intercourse exists between urban and rural residents (22.2 and 21.4 years, respectively). There is a one- to two-year difference between those who have secondary or higher education (22.5 years) and those who have less education (20.7-21.1 years). There is a difference of one year between men in the wealthiest quintile and men in the other quintiles (22.4 years compared with a little over 21 years).

8.4 RECENT SEXUAL ACTIVITY

In addition to age at first sexual intercourse, in the absence of effective contraception, exposure to pregnancy depends on the pattern of sexual activity. The most important factors are frequency of intercourse, postpartum abstinence, and abstinence for reasons other than being postpartum. Information on recent sexual activity, therefore, can be used to refine measures of exposure to pregnancy. Table 8.6.1 shows the pattern of sexual activity among women in the four weeks preceding the survey by background characteristics, and Table 8.6.2 shows the patterns among men.

Table 8.6.1 Recent sexual activity: women

Percent distribution of women by timing of last sexual intercourse, according to background characteristics, Cambodia 2005

¹ Excludes men who had sexual intercourse within the past 4 weeks
² Excludes men who are not currently married

About one-half (47 percent) of all women were sexually active during the four weeks preceding the survey; 12 percent had not had sex within the past four weeks, but had done so within the past year; and 8 percent of women had not had sex in one year or longer. The remaining 32 percent had never had sexual intercourse. The proportion of women who were sexually active in the four weeks prior to the survey increases with age up to age 30-34 and declines thereafter. The proportion

sexually active in the past four weeks by marital duration is correlated with the variance by age. It peaks at marital duration of 10-14 years (when women who married at the age of 20 would be 30-34 years old, for example) and declines thereafter. Higher proportions of rural women (49 percent) were sexually active than urban women (42 percent).

It is interesting, given that only 47 percent of women report being sexually active in the past four weeks, that 56 percent of men report the same. Eight percent of men had not had sex within the past four weeks, but had done so within the past year; and 3 percent of men had not had sex in one year or longer. About the same proportion of men as women have never had sex: 33 percent. The proportion of men who were sexually active in the four weeks prior to the survey increases with age up to age 40-44, with 91 percent of men reporting sex in the past 4 weeks. The proportion of men sexually active in the four weeks prior to interview peaks at a marital duration of 10-14 years and declines thereafter. About the same proportions of rural men were sexually active (56 percent) as urban men (54 percent). Regarding education, the proportion recently sexually active falls from 75 percent among men with no education to 49 percent among women with secondary education or higher. Regarding wealth, those in the lowest two quintiles engaged in recent sexual activity more frequently than did those in the middle or higher quintiles. But as with women, both education and wealth are inversely related to the percentage who have never had sexual intercourse, such that the percentage of men who have never had sexual intercourse rises steadily with increasing education and wealth quintile. Recent sexual activity among men ranges from a low of 48 percent in Pursat to a high of 63 percent in Kratie.

8.5 POSTPARTUM AMENORRHEA, ABSTINENCE, AND INSUSCEPTIBILITY

Postpartum amenorrhea refers to the interval between childbirth and the resumption of ovulation, a period during which a woman is temporarily infecund. The length and intensity of breastfeeding influences the duration of postpartum amenorrhea, as has been shown in various studies. Women are considered insusceptible if they are not exposed to the risk of pregnancy, either because they are amenorrheic or are abstaining from sexual intercourse after a birth. Table 8.7 shows the percentage of births born in the three years prior to the survey for which their mothers are amenorrheic, abstaining from sex, and insusceptible, by the number of months since the child was born.

In Cambodia, the typical length of postpartum amenorrhea is considerably longer than the typical length of postpartum abstinence and is the major determinant of postpartum insusceptibility to pregnancy. Cambodian women are insusceptible for a median period of 9.9 months, amenorrheic for a median period of 9.3 months, and abstain after childbirth for a median duration of 3.4 months. Twenty-nine percent of mothers to recently born children are postpartum amenorrheic, ranging from 98 percent within 2 months of birth, to 55 percent at 8-9 months postpartum. Ninety-six percent of mothers are still abstaining within two months of their births; by 6-7 months postpartum, 17 percent of new mothers

Table 8.7 Postpartum amenorrhea, abstinence and insusceptibility

Note: Estimates are based on status at the time of the survey.
na = Not applicable

are abstaining postpartum. Eighty percent of mothers with recent births remain insusceptible to pregnancy through their fifth month postpartum.

Table 8.8 shows the median duration of postpartum amenorrhea, abstinence, and insusceptibility to pregnancy according to background characteristics. The duration of postpartum insusceptibility is longer by about a month among women in the 30-49 age group than among those age 15-29. Rural and urban women abstain from sexual relations for the same amount of time (3.4 months). However, rural women experience postpartum amenorrhea that is, on average, longer by two months than women living in urban areas (9.6 and 7.7 months, respectively). Women living in Phnom Penh experience the shortest period of postpartum amenorrhea (4.6 months). Phnom Penh is also among the provinces with the shortest duration of postpartum abstinence (2.4) and thus the shortest duration of insusceptibility (5.9 months). Women living in Takeo have the longest period of postpartum amenorrhea (12.6 months), while women living in Kratie have the longest period of postpartum abstinence (5.0 months). Prey Veng and Kampong Thom have the longest total period of postpartum insusceptibility, with a median of 13.3 months. Women in the highest educational and wealth categories have the shortest periods of postpartum insusceptibility.

8.6 TERMINATION OF EXPOSURE TO PREGNANCY

The risk of childbearing declines as age increases. The term infecundity denotes a process rather than a well-defined event. Although the onset of infecundity is difficult to determine for an individual woman, there are ways of estimating it for a group of women. Table 8.9 presents data on menopause, an indicator of decreasing exposure to the risk of pregnancy (infecundity) for women age 30 and over.

A woman is considered menopausal if she is not pregnant, not postpartum amenorrheic, and did not have a menstrual period for at least six months before the survey. Eleven percent of Cambodian women age 30-49 are menopausal. As expected, the proportion of women who reached menopause increases with age, particularly after age 45. It rises from 11 percent among women age 44-45 to 41 percent among women at the end of their reproductive years (age 48-49).

Age	Percentage menopausal ¹	Number of women
30-34	4.0	2,082
35-39	5.6	2,229
40-41	5.6	840
42-43	8.3	857

46-47	24.6	725
48-49	40.8	663
Total	10.5	8,126

¹ Percentage of all women who are not pregnant and not postpartum amenorrheic whose last menstrual period occurred six or more months preceding the survey

FERTILITY PREFERENCES

The 2005 CDHS collected information on fertility preferences to measure the overall attitudes of women toward childbearing and the general course of future fertility. Data on fertility preferences are also useful for assessing the unmet need for family planning and the number of unwanted or mistimed births in the population. These, together with data on contraceptive prevalence, provide an estimation of the demand for family planning.

9.1 DESIRE FOR MORE CHILDREN

Currently married women in Cambodia were asked whether they want to have a child (or another child), and if so, how soon. Table 9.1 presents fertility preferences among currently married women by number of living children. Thirty-five percent of currently married women state that they want to have another child; this is a considerable increase from the 2000 CDHS, in which 24 percent of women stated that they wanted to have another child. Ten percent of women want to have a child within two years, 23 percent prefer to wait for two years or more to have another child, and 2 percent want another child but are undecided as to when they want to have that child. The majority of married women want no more children, (57 percent want no more or have been sterilized). This is a considerable increase from 37 percent wanting no more children in the 2000 CDHS. At the time of the 2000 CDHS, 28 percent of women reported that they did not know whether or not they wanted another child. Currently, only 4 percent of married women are undecided about whether they want more children. The information presented in Table 9.1 indicates that among women who would like to have another child, many prefer to space their pregnancies, and are potentially in need of family planning for that purpose, as are the large proportions of women who express the desire to limit their births.

Table 9.1 Fertility preferences by number of living children

² Wants next birth within 2 years

³ Wants to delay next birth for 2 or more years

⁴ Includes both female and male sterilization

Table 9.2 displays the percentage of currently married women who want no more children by number of living children and background characteristics. The proportion of currently married women who want no more children is relatively large (57 percent). Desire to limit childbearing increases with increasing number of living children, from 4 percent among married women with no living children to 85 percent among women with six or more living children. There are particularly significant increases

in the proportion of women wanting no more children between parities one and two (a difference of 35 percentage points; 2000 CDHS: 20 percentage points) and parities two and three (a difference of 23 percentage points). The large proportion of women indicating a desire to have no more children at parities two and three may indicate the existence of an ideal family size of two to three children.

It is interesting to note that 61 percent of women with no education want no more children, while 48 percent of women with secondary or higher education want the same. There is considerable variation across provinces; Kampong Speu has the smallest proportion of women wishing to curtail their fertility (39 percent), while Prey Veng has the highest proportion (69 percent). There is surprisingly little variation in women's desire to stop childbearing by urban/rural residence (59 percent and 57 percent, respectively) or by wealth (59 percent of the poorest women wish to cease childbearing, compared with 56 percent of the wealthiest).

Note: Women who have been sterilized are considered to want no more children. Figures in parentheses are based on 25-49 unweighted cases. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.

¹ Includes current pregnancy

9.2 NEED FOR FAMILY PLANNING SERVICES

Women who are currently married and who say either they want no more children or want to wait at least two years before having another child, but are not using contraception, are considered to have an unmet need for family planning. Women who are currently using family planning methods are said to have a met need for family planning. The sum of women with unmet need and met need constitutes the total demand for family planning.

Table 9.3 presents the demand for family planning services by background characteristics. Twenty-five percent of currently married women have an unmet need for family planning, with 9 percent having an unmet need for spacing and 16 percent having an unmet need for limiting. These numbers are considerably lower than the corresponding data collected in the 2000 CDHS, when 33 percent of currently married women had an unmet need for family planning. Most of the change in need over time occurred in the need for family planning for spacing: 17 percent of women had an unmet need for spacing in 2000, as compared with 9 percent of women with an unmet need for spacing in 2005. While in 2000, only 24 percent of women had a met need for family planning, that proportion increased significantly by 2005, with 40 percent of women having a met need for family planning. Increased met need has occurred even in the context of an increase in the total demand for family planning, from 56 percent in 2000 to 65 percent in 2005. These findings support the legitimacy of the 2005 CDHS data that reflect a decline in fertility, as discussed in Chapter 5.

The level of unmet need for spacing decreases with age, while the opposite is true for unmet need for limiting. The total unmet need for family planning varies little by age group among women younger than 45 years but falls for women age 45-49. Demand for family planning is highest among women age 30-39, with about three-quarters of women in this age range having a demand for family planning.

Unmet need is higher among rural women than among urban women (26 percent and 22 percent, respectively). Across provinces, the overall unmet need for family planning is highest in Banteay Mean Chey (33 percent) and lowest in Phnom Penh (16 percent). The highest provincial level of unmet need found in the 2000 CDHS was 50 percent, in Kampong Chhnang. Whereas unmet need for spacing remains about the same as the level of education increases, unmet need for limiting is negatively associated with education. Women with the highest levels of education have both the highest demand for family planning (70 percent) and the highest percentage of demand satisfied (72 percent). Women in the highest wealth quintile also have both the highest demand for family planning (71 percent) and the highest percentage of demand satisfied (76 percent).

Table 9.3 Need and demand for family planning among currently married women

Percentage of currently married women with unmet need for family planning, percentage with met need for family planning, the total demand for family planning, and the percentage of the demand for contraception that is satisfied, by background characteristics, Cambodia 2005

¹ *Unmet need for spacing* includes pregnant women whose pregnancy was mistimed, amenorrheic women who are not using family planning and whose last birth was mistimed, or whose last birth was unwanted but now say they want more children, and fecund women who are neither pregnant nor amenorrheic, who are not using any method of family planning, and say they want to wait 2 or more years for their next birth. Also included in *unmet need for spacing* are fecund women who are not using any method of family planning and say they are unsure whether they want another child or who want another child. *Unmet need for limiting* refers to pregnant women whose pregnancy was unwanted, amenorrheic women who are not using family planning, whose last child was unwanted and who do not want any more children, and fecund women who are neither pregnant nor amenorrheic who are not using any method of family planning and who want no more children.

² *Using for spacing* is defined as women who are using some method of family planning and say they want to have another child or are undecided whether to have another. *Using for limiting* is defined as women who are using and who want no more children. Note that the specific methods used are not taken into account here.

9.3 IDEAL FAMILY SIZE

Information on the ideal family size was collected in two ways. Respondents who had no living children were asked how many children they would like to have if they could choose the number of children to have. Respondents with children were asked how many children they would like to have if they could go back to the time when they did not have any children and could choose exactly the number of children to have. Even though these questions are based on hypothetical situations, they give an idea of the total number of children women who have not started childbearing will have in the future, and among older and high parity women, these data provide a measure of the level of unwanted fertility.

Table 9.4 shows that the majority of respondents were able to provide a numeric response to these questions. Three percent of women gave nonnumeric responses such as “any number,” “depends on fate,” or “do not know.” Among women with no living children, 38 percent would like to have 2 children, 26 percent would like to have 3 children, and 20 percent would like to have 4. Only 6 percent of women with no living children want 5 or more children. As women’s actual family sizes increase, so too do their ideal family sizes: only among those who have 6 or more children do as many as one-fifth of mothers state that 6 or more children was their ideal family size. The mean ideal family size for all women also shows a positive association with the number of living children: it increases from 2.8 children among childless women to 4.6 children among women with 6 or more children. The observed positive association between the ideal family size and the number of living children may arise for several possible reasons. First, women may tend to rationalize their family size by reporting their actual number of children as their ideal number, or second, they may have achieved their preferred number of children. A third possibility is that there has been a decrease of ideal family size in the youngest cohorts. The average ideal family size among all women who gave numeric responses is 3.3 while it is 3.6 children among currently married women.

Table 9.4 Ideal number of children

¹ Includes current pregnancy

² Means are calculated excluding women who gave non-numeric responses.

The mean ideal number of children for all women by five-year age groups and background characteristics is shown in Table 9.5. The mean ideal number of children increases with increasing age, from 2.8 children for women age 15-19 to 4.1 children for women age 45-49. The mean ideal number of children among rural women is only somewhat higher than among their urban counterparts. Women in Phnom Penh have the lowest mean ideal number of children (2.8), but it is only an average of one child less than the regions with the highest mean ideal number of children (Mondol Kiri/Rattanak Kiri and Kampong Speu with 3.8 children). The mean ideal family size varies negatively with education but by no more than half a child. Women in the wealthiest quintile have a slightly smaller ideal family size than women from the other quintiles (3.0 for the wealthiest quintile as compared with about 3.5 for the other quintiles).

9.4 FERTILITY PLANNING

The 2005 CDHS provides an opportunity to estimate levels of unwanted fertility. Unwanted fertility can be estimated in one of two ways. Women were asked a series of questions about each of their children born in the five years preceding the survey, as well as any current pregnancy, to determine whether the pregnancy was wanted then (planned), wanted later (mistimed), or not wanted (unplanned) at the time of conception. This information may in fact underestimate unplanned childbearing since women may rationalize unplanned births and declare them as planned once they occur. Another way of measuring unwanted fertility utilizes the data on ideal family size to calculate what the total fertility rate would be if all unwanted births were avoided. This measure may also suffer from underestimation to the extent that women are unwilling to report an ideal family size lower than their actual family size.

Table 9.6 shows that 19 percent of births in the five years preceding the survey were not wanted, down from 24 percent of births being not wanted in the 2000 CDHS. Nine percent of births were mistimed (wanted later); this figure has not changed since 2000. The proportion of unwanted births rises with birth order, more than doubling from 3 percent among first-order births to 11 percent among second-order births, increasing to 18 percent among third-order births, and making the largest jump between third- and fourth- and higher-order births, at which parity 37 percent of births are unwanted. The same pattern seen in the comparison of differentials between planning statuses by parity also occurs in the planning status differentials by age: the percentage of unwanted births rises with mother's age.

Total	72.1	9.3	18.6	100.0	8,782

Note: Figures in parentheses are based on 25-49 unweighted cases.

Table 9.7 shows wanted fertility rates calculated using the second approach to measuring unwanted fertility. The wanted fertility rate is computed in the same way as the total fertility rate, except that unwanted births are excluded from the numerator. In this case, unwanted births are those that exceed the number mentioned as ideal by the respondent. This rate represents the level of fertility that would have prevailed in the five years preceding the survey if all unwanted births had been prevented.

The overall total wanted fertility rate is 2.8 children; it is about half a child lower than the actual total fertility rate of 3.4 children in the country. This is an improvement from 2000, when the difference between the wanted and actual fertility rates was one child. Overall, the gap between wanted and observed fertility is larger when the total fertility rate is still high, as can be observed by comparing figures across provinces. The gap between wanted and actual fertility is one child or greater in Battambang & Krong Pailin (a difference of 1.2 children), Preah Vihear & Steung Treng and Siem Reap (a difference of 1.1 children) and in Mondol Kiri/Rattanak Kiri (a difference of 1.0 children). Women in Kampong Cham and Takeo come closest to attaining their ideal fertility, with differences between wanted fertility rates and actual fertility rates of 0.4 children.

The gap between wanted and observed fertility rates is greater among women living in rural areas than in urban areas, likely indicating that women in rural areas have the desire to limit their births but may not have sufficient access to contraceptive technology. The difference between the two fertility rates is lowest among women with secondary and higher education and highest among women with no education, a finding that likely indicates an urbanization effect: women are more likely to be educated in urban areas, and women are also more likely to have access to modern contraceptive methods in urban areas, thus producing an association between education and greater propensity toward achieving desired fertility.

Table 9.7 Wanted fertility rates

Total wanted fertility rates and total fertility rates for the three years preceding the survey, by background characteristics, Cambodia 2005

Highest	2.0	2.4
Total	2.8	3.4

Note: Rates are calculated based on births to women age 15-49 in the period 1-36 months preceding the survey. The total fertility rates are the same as those presented in Table 5.2.

Estimates of maternal mortality require a comprehensive and accurate reporting of maternal deaths. Such reporting can be obtained through vital registration, longitudinal studies of pregnant women, or repeated household surveys. The 2005 CDHS is the second population-based national survey to incorporate questions on maternal mortality, the first was just five years prior in the 2000 CDHS. CDHS asked female respondents a series of questions designed with the explicit purpose of providing the necessary information to make direct estimates of maternal mortality.

However, in order to avoid serious misinterpretation of the results of the survey, it is crucial for users of this information to understand the problems inherent in measuring maternal mortality. Direct estimates of maternal mortality rely on data on the age of surviving sisters of survey respondents, the age at death of sisters who have died, and the number of years that have passed since the death of the sisters. CDHS interviewers listed all the brothers and sisters born to the natural mother of female respondents, in chronological order, starting with the first born. Information was then obtained on the survivorship of each of the siblings, the ages of surviving siblings, the year of death or years since death of deceased siblings, and the age at death of deceased siblings. For each sister who died at age 12 or above, the respondent was asked additional questions to determine whether the death was maternity related, that is, whether the sister was pregnant when she died, and if so, whether the sister died during childbirth, and if not, whether the sister died within two months of the termination of a pregnancy or childbirth. Listing all siblings in chronological order of their birth is done with the intention of improving the completeness of reporting. Collecting data on both male and female siblings also allows the direct estimation of adult male and female mortality.

10.1 DATA QUALITY ISSUES

The estimation of adult and maternal mortality requires reasonably accurate reporting of the number of sisters and brothers the respondent ever had, the number that have died, and the number of sisters who died of maternity-related causes. There is no definitive procedure for establishing the completeness or accuracy of retrospective data on sibling survivorship. Table 10.1 shows the number of siblings reported by female respondents, and the completeness of the reported data on current age, age at death, and years since death.

Sibling	Sisters		Brothers		All siblings	
	Number	Percent	Number	Percent	Number	Percent
All siblings	44,039	100.0	46,040	100.0	90,079	100.0
Surviving	36,068	81.9	34,493	74.9	70,561	78.3
Dead	7,733	17.6	10,975	23.8	18,708	20.8
Missing survival information	238	0.5	572	1.2	810	0.9
Living siblings	36,068	100.0	34,493	100.0	70,561	100.0
Age reported	36,036	99.9	34,464	99.9	70,500	99.9
Age missing	32	0.1	29	0.1	61	0.1
Dead siblings	7,733	100.0	10,975	100.0	18,708	100.0
AD and YSD reported	7,627	98.6	10,777	98.2	18,403	98.4
AD missing	17	0.2	22	0.2	39	0.2

Both AD and YSD missing	71	0.9	154	1.4	225	1.2

As a group, CDHS female respondents were able to report the survival status of 99 percent of their siblings; whether or not a brother or sister was alive or dead was unknown for 0.9 percent of siblings. Sex ratio is defined as the number of males per 100 females. The sex ratio of siblings who have died is calculated as the number of brothers per 100 sisters: 10,975 brothers who died compared with 7,733 sisters who died. The sex ratio of siblings who have died was 142, which is very high and may be the consequence of the higher male mortality during the Khmer Rouge period. Fighting in the post-Khmer Rouge period continued until the signing of the Paris Peace Accord in 1993; this fighting would have also contributed to the high sex ratio of dead siblings. Overall, the data on siblings is nearly complete with age reported for 99.9 percent of living siblings and an age at death and years since death reported for 98.4 percent of siblings who have died, with little difference between brothers and sisters. Rather than exclude siblings with missing information from the analysis, the information on the birth order of siblings, in conjunction with other information, is used to impute the missing data.¹

Another crude measure of data quality is the mean number of siblings, or the mean sibship size (Table 10.2). Sibship size is expected to decline as fertility declines over time. The monotonic decline in sibship size that would be expected to accompany declining fertility is supportive of more complete reporting of older siblings. Sex ratios at birth fall within the internationally accepted range of 103 to 105 for most but not all five-year periods, indicating there is no serious underreporting or overreporting of brothers or sisters. However, it should be borne in mind that any information that relies on recall will suffer from some degree of misreporting, especially if it pertains to deceased persons and occurred a long time before the survey.

Respondent's year of birth	Mean sibship size	Sex ratio at birth of siblings
1955-59	6.6	103.4
1960-64	6.5	107.6
1965-69	6.6	102.4
1970-74	6.6	99.0
1975-79	6.5	104.5
1980-84	6.4	108.2
1985-89	5.9	105.1
Total	6.4	104.6

10.2 ADULT MORTALITY

Because maternal mortality is a subset of adult mortality, we first estimate overall adult mortality. If overall adult mortality estimates display a general, stable, and plausible pattern, then credence is given to the maternal mortality estimates derived thereafter.

Direct estimates of male and female adult mortality are obtained from information collected in the sibling history. Age-specific death rates are computed by dividing the number of deaths in each age group by the total person-years of exposure in that age group during a specified reference period. In total, female respondents reported 90,079 siblings, of whom 44,039 were sisters and 46,040 were brothers (Table 10.1). Direct estimates of age-specific mortality rates for males and females are shown in Table 10.3. To minimize the impact of possible heaping on years since death ending in zero and five, direct estimates are presented for the period 0-6 years before the survey, which roughly corresponds² to January 1999 through December 2005. Aggregating the data over the age range 15-49 will reduce the effects of sampling variability. There are more male than female deaths in the seven years preceding the survey (860 compared with 574). The male mortality rate is 5.2 deaths per 1,000 population and it is higher than the female mortality rate of 3.1 deaths per 1,000 population.

¹ The imputation procedure is based on the assumption that the reported birth ordering of the siblings in the birth history is correct. The first step is to calculate birth dates. For each living sibling with a reported age and for each dead sibling with complete information on both age at death and year of death, the birth date is calculated. For a sibling missing these data, a birth date is imputed within the range defined by the birth dates of the bracketing siblings. In the case of living siblings, an age is calculated from the imputed birth date. In the case of dead siblings, if either age at death or year of death is reported, that information is combined with the birth date to produce missing information. If both pieces of information are missing, the age at death is imputed. This imputation is based on the distribution of the ages at death for those whose year of death is unreported but age at death is reported.

² The time period is not exact because as with all DHS calculations of exposure time, exposure is calculated separately for each respondent, counting back in time from the date of interview, and dates of interview in the CDHS spanned a time of six months.

^a Age-adjusted rate

10.3 MATERNAL MORTALITY

Estimates of maternal mortality for the period 0-6 years before the survey are shown in Table 10.4. This period of time was chosen to reduce possible heaping of reported years since death on five-year intervals. Age-specific mortality rates are calculated by dividing the number of maternal deaths by years of exposure. To remove the effect of truncation bias (the upper boundary for eligibility in the 2005 CDHS is 49 years), the overall rate for women age 15-49 is standardized by the age distribution of the survey respondents. Maternal deaths are defined as any death that occurred during pregnancy, childbirth, or within two months after the birth or termination of a pregnancy. This time-specific definition includes all deaths that occurred during the specified period even if the death is due to nonpregnancy-related causes. However, this definition is unlikely to result in over-reporting of maternal deaths because most deaths to women in the specified period are due to maternal causes, and maternal deaths in general are more likely to be under-reported than over-reported. For any given age group, maternal deaths are a relatively rare occurrence, and as such, the age-specific pattern should be interpreted with caution

There were 98 maternal deaths in the seven years preceding the survey. The maternal mortality rate, which is the annual number of maternal deaths per 1,000 women age 15-49, for the period 1999-2005 is 0.50. Maternal deaths accounted for 17 percent of all deaths to women age 15-49; in other words, about one in six Cambodian women who died in the seven years preceding the survey died from pregnancy or pregnancy-related causes. Maternal deaths still account for the same

proportion of overall deaths as they have in the recent past, as the 2000 CDHS found that maternal deaths accounted for 18 percent of all female deaths in the seven years prior to the survey.

The maternal mortality ratio, obtained by dividing the age-standardized maternal mortality rate by the age-standardized general fertility rate, is often considered a more useful measure of maternal mortality since it measures the obstetric risk associated with each live birth. Table 10.4 shows that the maternal mortality ratio for Cambodia for the period 1999-2005 is 472 deaths per 100,000 live births (or alternatively, 4.72 deaths per 1,000 live births). The maternal mortality ratio can be converted to an estimate of the lifetime risk of dying from maternal causes: 0.02 or, in other words, a risk of dying of 1 in 50.

The 2000 CDHS found a maternal mortality ratio of 437 deaths per 100,000 live births (4.37 deaths per 1,000 live births), indicating there has been no change in maternal mortality since 2000.

² Expressed per 100,000 live births; calculated as the maternal mortality rate divided by the general fertility rate.
³ Lifetime risk of maternal death = $1 - (1 - \text{MMR}/100,000)^{\text{TFR}}$ where TFR represents the total fertility rate for the period 0-6 years prior to the survey (=3.6).
^a Age-adjusted rate

This chapter presents levels, trends, and differentials in neonatal, postneonatal, infant, and child mortality in Cambodia. Information on infant and child mortality rates not only enriches the understanding of a country's socioeconomic situation but also sheds light on the quality of life of the population under study. Studies of mortality indicators have shown the existence of differentials by socioeconomic and demographic characteristics; thus, the data in this report are disaggregated by these groupings.

Disaggregation of mortality indicators by different economic, social, and demographic categories helps to identify populations that are at high risk. Preparation, implementation, monitoring, and evaluation of population, health, and other socioeconomic programs and policies depend to a large extent on a target population. The data presented here can help identify at-risk populations and provide an indication of the current mortality situation, which can be compared with previously collected data to determine whether improvements in health and quality of life have occurred over time.

The mortality rates presented in this chapter are computed from information in the birth history section of the Women's Questionnaire. Each woman age 15-49 was asked whether she had ever given birth, and if she had, she was asked to report the number of sons and daughters who live with her, the number who live elsewhere, and the number who have died. In addition, she was asked to provide a detailed birth history of her children in chronological order starting with the first child. Women were asked whether a birth was single or multiple; the sex of the child; the date of birth (month and year, either by the Gregorian or Khmer calendar system); survival status; age of the child on the date of interview if alive; and if not alive, the age at death of each live birth. The rates of childhood mortality are expressed as deaths per 1,000 live births, except in the case of child mortality, which is expressed as deaths per 1,000 children surviving to age one. Childhood mortality rates are defined as follows:

- **Neonatal mortality:** the probability of dying within the first month of life
- **Postneonatal mortality:** the probability of dying between the first month of life and first birthday (computed as the difference between infant and neonatal mortality)
- **Infant mortality:** the probability of dying between birth and the first birthday
- **Child mortality:** the probability of dying between the first and fifth birthday
- **Under-five mortality:** the probability of dying between birth and the fifth birthday.

11.1 ASSESSMENT OF DATA QUALITY

The reliability of mortality estimates depends on the sampling variability of the estimates and on nonsampling errors. Sampling variability and sampling errors are discussed in detail in Appendix B. Nonsampling errors depend on the extent to which the date of birth and age at death are accurately reported and recorded and the completeness with which child deaths are reported. Omission of births and deaths affects mortality estimates, displacement of dates impacts mortality trends, and misreporting of age at death may distort the age pattern of mortality. Typically, the most serious source of nonsampling errors in a survey that collects retrospective information on births and deaths arises from an underreporting of both births and deaths of children who are not alive at the time of the survey. It may be that mothers are generally reluctant to talk about their dead children

because of the sorrow associated with any death, or they may live in a culture that discourages discussing the dead. Underreporting of births and deaths is generally more severe the further back in time an event occurred.

An unusual pattern in the distribution of births by calendar years is an indication of omission of children or age displacement. However, Table C.4 in Appendix C shows that the percentage of all births for which a month and year of birth was reported remains stable over time, ranging from 99.9 percent of births in 2006 to 97.5 percent of births prior to 1987. Although there is some difference in the reporting of a complete birth date between children who are alive (99 percent of births) and children who are dead (93 percent of births), this does not appear to have an effect on data quality.

Underreporting of deaths is usually assumed to be higher for deaths that occur very early in infancy. An examination of the ratios in Tables C.5 and C.6 show no significant number of early infant deaths being omitted in the 2005 CDHS. The proportion of neonatal deaths occurring in the first week of life (79 percent) and the proportion of infant deaths occurring during the first month of life (46 percent) are entirely plausible and in-line with the findings of the 2000 CDHS survey (70 percent and 42 percent, respectively). This indicates no evidence of selective underreporting or misreporting of age at death that would compromise the quality of the CDHS rates for childhood mortality.

11.2 LEVELS AND TRENDS IN CHILDHOOD MORTALITY

Table 11.1 presents neonatal, postneonatal, infant, child, and under-five mortality rates for five-year periods before the survey. Neonatal mortality in the most recent period is 28 deaths per 1,000 live births. This rate is significantly lower than postneonatal deaths (37 deaths per 1,000 live births) during the same period; that is, the risk of dying for any child who survived the first month of life increases during the period of the next 11 months. Thus, one in every 15 babies born in Cambodia (66 per 1,000) does not survive to his or her first birthday. Under-five mortality in Cambodia is 83 deaths per 1,000 live births.

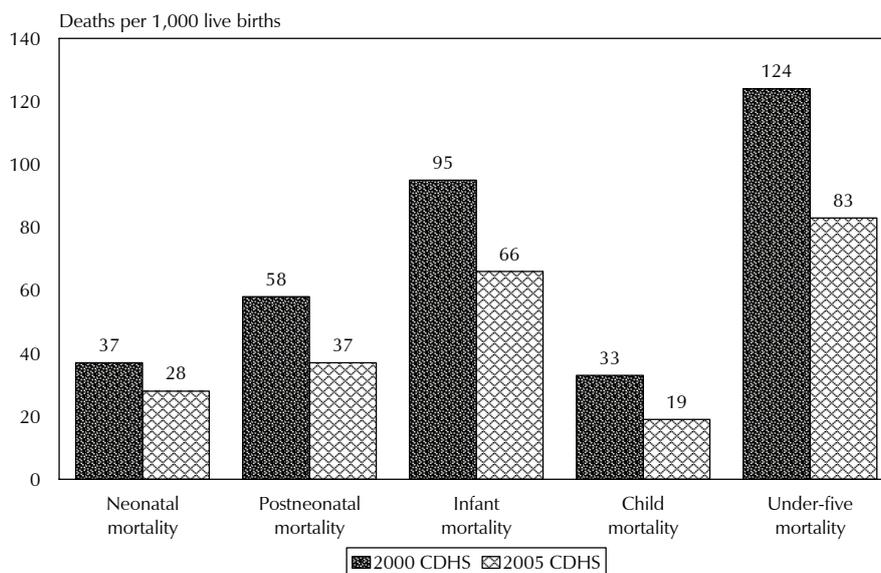

Years preceding the survey	Neonatal mortality (NN)	Postneonatal mortality ¹ (PNN)	Infant mortality (₁ q ₀)	Child mortality (₄ q ₁)	Under-five mortality (₅ q ₀)
0-4	28	37	66	19	83
5-9	43	65	109	21	127
10-14	44	50	93	34	124

¹ Computed as the difference between the infant and neonatal mortality rates

Table 11.1 shows that childhood mortality has declined substantially in the past five years. Between the two most recent five-year periods, infant mortality declined 39 percent, from 109 deaths per 1,000 live births in the period 5-9 years before the survey to 66 per 1,000 in the period 0-4 years before the survey. Under-five mortality also declined 35 percent in the same period from 127 deaths per 1,000 live births to 83 per 1,000.

Another way of looking at trends in mortality rates is a comparison of the results of the 2005 CDHS with the findings from the 2000 CDHS, in which data were collected using the same techniques, and estimates were calculated using the same methodology. Figure 11.1 compares childhood mortality rates for the five-year period preceding the 2000 CDHS and the 2005 CDHS and shows a significant drop in each of the childhood mortality rates.

Figure 11.1 Trends in Childhood Mortality, 2000 and 2005 CDHS

Figures 11.2 through 11.4 show in more detail the evolution of infant, child, and under-five mortality trends for several five-year periods preceding the 2000 CDHS and the 2005 CDHS. Infant mortality and under-five mortality have both declined significantly over the past 25 years, with the most dramatic declines coming since the late 1990s.

By comparing mortality estimates from the 2000 and 2005 CDHS for the 0-4, 5-9, and 10-14 years prior to each survey, it can be seen that the estimates from the two CDHS surveys are comparable. Infant mortality in the late 1990s was estimated to be 109 deaths per 1,000 live births by the 2005 CDHS (September 1995-March 2001), and 95 deaths per 1,000 live births by the 2000 CDHS (February 1995-July 2000). Infant mortality in the early 1990s was estimated to be 93 deaths per 1,000 live births by the 2005 CDHS (September 1990-March 1996) and 91 deaths per 1,000 live births by the 2000 CDHS (February 1990-July 1995). The under-five mortality data from the two surveys are even more similar. Under-five mortality in the late 1990s was estimated to be 127 deaths per 1,000 births by the 2005 CDHS (September 1995-March 2001), and 124 deaths per 1,000 live births by the 2000 CDHS (February 1995-July 2000). Under-five mortality in the early 1990s was estimated to be 124 deaths per 1,000 births by the 2005 CDHS (September 1990-March 1996), and 119 deaths per 1,000 live births by the 2000 CDHS (February 1990-July 1995). Taken as a whole, this indicates a strong comparability of the childhood mortality data between the two CDHS surveys, lending further support to the conclusion that childhood mortality rates have indeed declined.

Figure 11.2 Trends in Infant Mortality

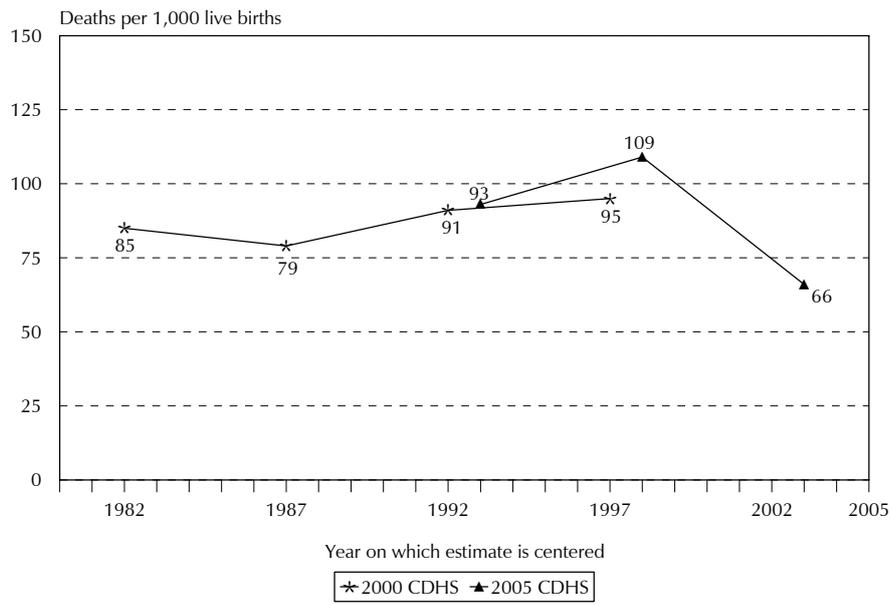

Figure 11.3 Trends in Child Mortality

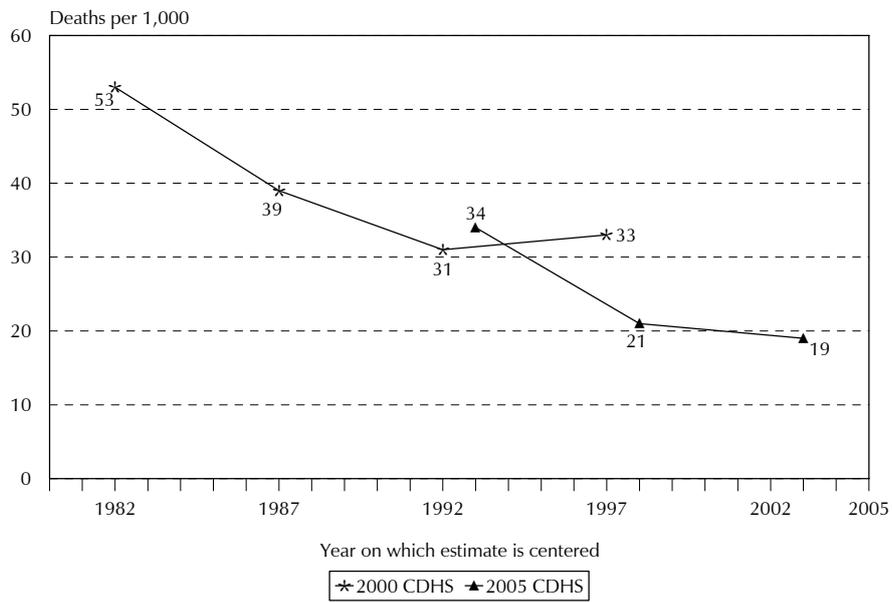

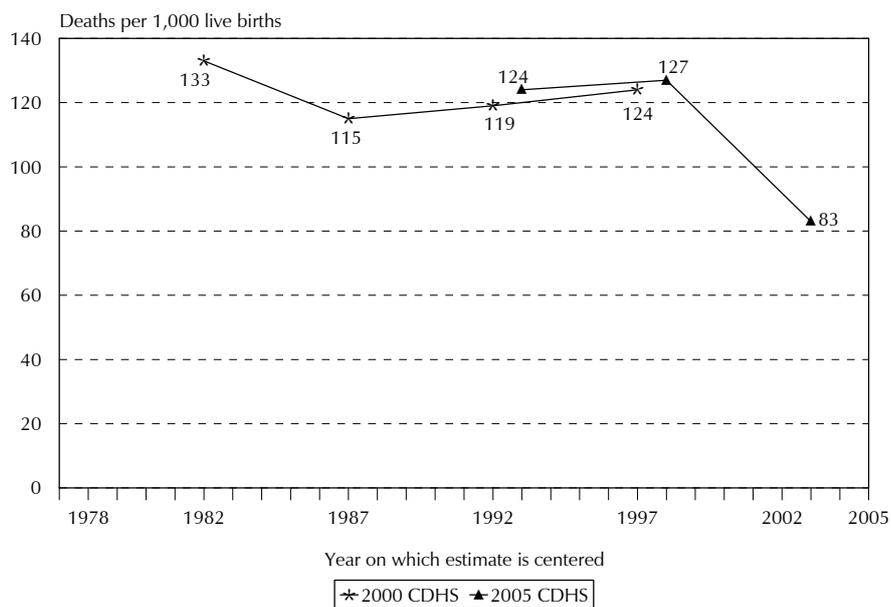

Figure 11.4 Trends in Under-five Mortality

11.3 SOCIOECONOMIC DIFFERENTIALS IN CHILDHOOD MORTALITY

From Table 11.2 and Figure 11.5, it is apparent that infant and child survival is influenced by the socioeconomic characteristics of mothers.¹ Mortality in urban areas is consistently lower than in rural areas. For example, infant mortality in urban areas is 65 deaths per 1,000 live births, compared with 92 deaths per 1,000 live births in rural areas—30 percent higher in rural areas than in urban areas. The urban-rural difference is somewhat greater in the case of child mortality, which is 43 percent lower in urban areas than in rural areas. Differentials in mortality by province are also pronounced, particularly when observing the large differences between the lowest and highest infant and under-five rates of mortality: Phnom Penh has an infant mortality rate of 42, while Prey Veng and Mondol Kiri/Rattanak Kiri have rates three times greater. Similarly, Phnom Penh’s under-five mortality rate is 52, while that of Mondol Kiri/Rattanak Kiri is 165.

¹ To have a sufficient number of cases to ensure statistically reliable mortality estimates, rates presented in Tables 11.2 and 11.3 are calculated for a ten-year period.

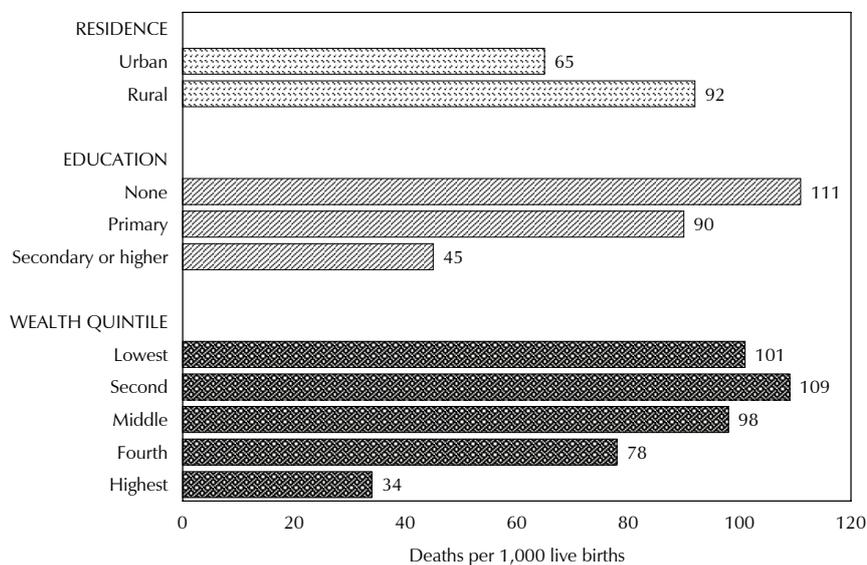

Table 11.2 Early childhood mortality rates by socioeconomic characteristics

¹ Computed as the difference between the infant and neonatal mortality rates

Figure 11.5 Infant Mortality by Mother's Background Characteristics

CDHS 2005

As expected, mortality declines markedly as mother's education increases. Children born to mothers with no education suffered the highest mortality; according to the survey results, children of educated mothers with secondary and higher levels of education experience 59 percent lower infant mortality and 61 percent lower under-five mortality, compared with mothers with no education.

In addition, mortality declines markedly as the wealth of the household increases. Children born in poorer households suffered higher mortality than those born in wealthier households; children living in the wealthiest households had infant and under-five mortality rates 66 percent lower than those living in the poorest households.

11.4 DEMOGRAPHIC DIFFERENTIALS IN MORTALITY

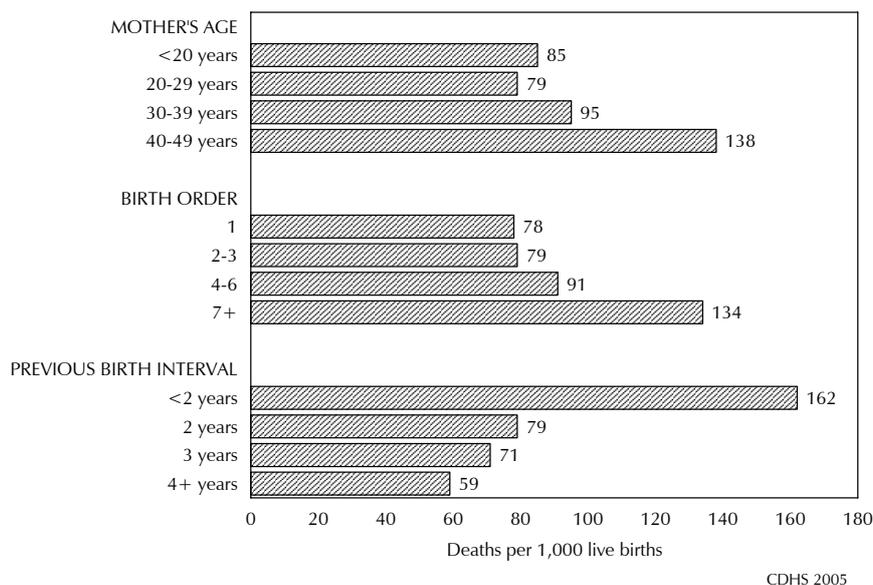

Infant and child mortality is also influenced to a considerable extent by demographic characteristics of mothers and children. Table 11.3 shows the relationship between childhood mortality and different demographic variables. At every period, male children experience higher mortality than female children. The gender difference is most pronounced in the first month of life; neonatal mortality among boys is 42 deaths per 1,000, compared with 30 deaths per 1,000 among girls. The excess mortality among boys is a universal phenomenon presumably due to a higher biological risk of death during the first months of life.

¹ Computed as the difference between the infant and neonatal mortality rates
² Excludes first-order births
³ Rates for the five-year period before the survey

The relationship between infant mortality and certain reproductive variables is illustrated in Figure 11.6. The relationship between maternal age at birth and childhood mortality is generally a U-shaped curve, being relatively higher among children born to mothers under age 20 and over age 40 than among mothers in the middle age groups. This pattern is especially obvious in the case of infant mortality, where mothers age 40-49 have children who experience an infant mortality rate considerably higher than that of younger mothers.

Figure 11.6 Infant Mortality by Selected Demographic Characteristics

While first-order births appear to be no more risky than second- or third-order births, significant increases in risk are most apparent for birth order seven and higher. Infant mortality rates for children of a seventh or higher birth order are twice that of a third or lower birth order child.

Short birth intervals also significantly reduce a child's chances of survival. For example, children born less than two years after a preceding birth are two-and-a-half times as likely to die within the first month of life as children born after just a two-year interval (71 deaths per 1,000 live births compared with 29 per 1,000). Infant mortality differentials are equally as striking; a child born less than two years after a preceding birth is 2.7 times as likely to die before his or her first birthday as a child born four or more years after a preceding birth.

Studies have shown that a child's weight at birth is an important determinant of its survival chances. Children's actual birth weights were unavailable for most children; instead, mothers were asked whether their child was very large, larger than average, average, smaller than average, or small at birth, since this has been found to be a good proxy for a child's weight at birth. Those children reported by their mother to be small or very small were almost three times more likely to die before the age of one month than those reported to be average or larger.

11.5 HIGH-RISK FERTILITY BEHAVIOR

The survival of infants and children depends in part on the demographic and biological characteristics of their mothers. Typically, the probability of dying in infancy is much greater among children born to mothers who are too young (under age 18) or too old (over age 34), children born after a short birth interval (less than 24 months after the preceding birth), and children born to mothers of high parity (more than three children). The risk is elevated when a child is born to a mother who has a combination of these risk characteristics.

Table 11.4 shows the percent distribution of children born to currently married women in the five years before the survey by these risk factors. Only 29 percent of births were not in any high-risk category. Twenty-four percent were first births to women between age 18 and 34—considered an unavoidable risk category—while 28 percent of births were in a single high-risk category, and 19 percent were in a multiple high-risk category. The most common single high-risk category was births of order three and above (15 percent), while the most common multiple high-risk category was births to mothers older than 34 years and of birth order three and above (13 percent).

Table 11.4 High-risk fertility behavior

Percent distribution of children born in the five years preceding the survey by category of elevated risk of mortality and the risk ratio, and percent distribution of currently married women by category of risk if they were to conceive a child at the time of the survey, Cambodia 2005

Risk category	Births in the 5 years preceding the survey		Percentage of currently married women assigned to the risk category ¹

Total	100.0	na	100.0
Number of births	7,789	na	10,087

Note: Risk ratio is the ratio of the proportion dead among births in a specific high-risk category to the proportion dead among births not in any high-risk category. Figures in parentheses are based on 25-49 unweighted cases. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.
na = Not applicable
¹ Women are assigned to risk categories according to the status they would have at the birth of a child if they were to conceive at the time of the survey: current age less than 17 years and 3 months or older than 34 years and 2 months, latest birth less than 15 months ago, or latest birth being of order 3 or higher.
² Includes the category age <18 and birth order >3
^a Includes sterilized women

The risk ratios displayed in the second column of Table 11.4 denote the relationship between risk factors and mortality. For example, the risk of dying for a child who falls into any of the avoidable high-risk categories is 1.8 times that for a child not in any high-risk category. In general, risk ratios are higher for children in a multiple high-risk category than in a single high-risk category. Most vulnerable are children born of a mother older than age 34, who were born less than 24 months after a preceding birth and of a birth order greater than 3; they are nearly four times as likely to die as children who are not in any high-risk category. However, only 2 percent of births fall into this category. Among the single high-risk categories, having a mother age 34 or older results in a child having more than twice the risk of dying than children not in any high-risk category.

The final column of Table 11.4 illustrates the potential currently married women have for experiencing a high-risk birth. A woman's status at the time of the survey with regard to her age, time elapsed since the last birth, and parity, are used to classify her into the risk category she would fall if

she were to become pregnant at the time of the survey. For example, if a respondent who is age 40, has had four births and had her last birth 12 months ago were to become pregnant, she would fall into the multiple high-risk category of being too old, too high parity (four or more births), and giving birth too soon (less than 24 months) after a previous birth.

Overall, the majority of currently married women (74 percent) have the potential of giving birth to a child at elevated risk of mortality. About one in four women has the potential for having a birth in a single high-risk category, while about half of women have the potential for having a birth in a multiple high-risk category (mainly older maternal age and high birth order).

12.1 INTRODUCTION

The cause of death module was administered to all women eligible for the individual interview living in a 50 percent subsample of households selected for the 2005 CDHS. The cause of death module is also known as the verbal autopsy module. It was expected that the 50 percent subsample would provide a sufficient number of cases for analysis and was chosen to create a necessary balance between interviewer workload and data requirements. Survey findings indicate that recent mortality has declined to levels lower than was expected at the time of survey design.

Out of the 14,243 households interviewed in the CDHS, women living in the 50 percent subsample of 7,090 households were eligible for the cause of death module. This resulted in 8,417 women reporting on 3,048 live births since January 2002, 191 of which died prior to the survey. Thus, the number of cases for an analysis of causes of death is rather small.

12.2 CAUSE OF DEATH REPORTED BY THE MOTHER

Table 12.1 shows the distribution of 191 deaths among infants and young children by cause of death reported by the mother. These are all the deaths among live births occurring since January 2002. The cause of death reported by the mother was in response to an open-ended question “What do you think was the cause of (NAME)’s death?” posed without any mention of symptoms by the interviewer. The woman’s response was recorded in the questionnaire and categorized at a later date.

Table 12.1 Causes of death among infants and young children

Percent distribution of deaths among infants and children born since January 2002 by cause of death reported by the mother, according to age at death, Cambodia 2005

Cause of death reported by mother	Born since January 2002 and died at age <1 month (neonatal)	Born since January 2002 and died at age >1 month (postneonatal)	All deaths among infants born since January 2002

Accident	6.1	5.2	5.6
Total	100.0	100.0	100.0
Number of deaths	79	112	191

Only 10 percent of women reported that they did not know the cause of death, although mothers are more likely to report not knowing the cause of neonatal deaths (17 percent) than deaths among older infants and children (5 percent). The most commonly reported causes of death are: baby being premature, fever, illness of the respiratory system, dengue hemorrhagic fever, accidents, and tetanus type convulsions (each reported for 5 to 11 percent of deaths).

Table 12.2 shows the same deaths, categorized by whether a diagnosis was made by a health worker. Overall, 38 percent of deaths were diagnosed by a health worker. This and all subsequent tables exclude deaths reported as due to accident (11 cases), and include only deaths due to illness, or deaths due to accident at birth/prematurity/malformation at birth.

Table 12.2 Infant and child deaths diagnosed by a health worker

Percent distribution of deaths among infants and young children born since January 2002 by whether a diagnosis was made by a health worker, according to cause of death reported by the mother, Cambodia 2005

Cause of death reported by mother	Diagnosis by a health worker			Total	Number of deaths ¹ among infants and young children born since January 2002

¹ Excludes deaths due to accident.

12.3 SYMPTOMS PRIOR TO DEATH

In order to estimate probable cause of death it is necessary to know what symptoms the infant presented during the illness that led to death. Mothers were asked a series of direct yes/no questions inquiring whether they saw specific symptoms during the illness that led to the death of their child. Symptoms are not mutually exclusive, an infant may present with multiple symptoms.

Table 12.3 shows the percentage of deaths that were preceded by specific symptoms. Twenty-seven percent of neonatal deaths were among infants that suckled normally during the first two days of life and then had difficulty suckling during the days prior to death. Nineteen percent of neonatal deaths were babies born after a difficult labor or delivery. Eighteen percent of neonates were malformed in some way. Eighteen percent of neonatal deaths had convulsions or spasms during the illness that led to death.

Causes of death among infants and children age one month or older are different, and thus present different symptoms. Two-thirds of these deaths were preceded by a period of fever, a common symptom of many illnesses. The next most commonly reported symptoms were cough (42 percent), severe fever (41 percent), and convulsions (40 percent). One-quarter were extremely thin during the illness prior to death and 16 percent had swelling in their feet or legs, common symptoms of malnutrition. Prior to death, one in five presented with a skin rash on the face or body, a symptom shared by those with measles, although neither exclusive to measles nor necessary in contracting measles.

Table 12.3 Symptoms during illness that led to death

Proportion of dead children born since January 2002 who presented with specific symptoms during the illness that led to death, or who were born after a difficult labor or delivery, according to age at death, Cambodia 2005

Symptom	Percentage of deaths that were preceded by specific symptoms
Age at death: <1 month (neonatal)	
Difficult delivery	19.2
Malformation	18.1
Normal sucking then could not suck	26.6
Convulsions, spasms	17.6
Cough	4.5
Cough and rapid breathing	4.5
Tetanus	3.7
Number of deaths	74
Age at death: >1 month or older	
Diarrhea	31.1
Diarrhea (severe)	20.3
Diarrhea and blood in stool	4.8
Cough	41.5
Cough and rapid breathing	36.9
Fever	66.0
Severe fever	40.5
Unconscious	26.0
Convulsions	39.5
Skin rash on body /face	20.4
Extremely thin	25.7
Swelling feet/legs	15.5
Bleeding nose/ mouth/gums	4.2
Black vomiting or bloody stool	10.4
Discharge from eyes	4.2
Number of deaths	106

Note: Multiple symptoms are possible.

12.4 POSSIBLE CAUSE OF DEATH ON THE BASIS OF SYMPTOMS

Using the symptoms observed by mothers, it is possible to create an algorithm to establish a possible diagnosis of cause of death. The more specific the algorithm, the more likely the diagnosis is of being correct; on the other hand, the more specific the algorithm the fewer the number of cases. In addition, only a limited number of questions were posed regarding symptoms, thereby making it possible to identify only a limited number of illnesses. Ten questions were posed regarding to symptoms among neonates, and 23 questions could potentially be asked regarding the illness that led to death among older infants and children. Questions posed for neonates may be fewer than 23 because the response to one question may make a subsequent question not applicable, and therefore was not asked. For example, only mothers who reported their infant had a cough would be asked for how long the cough lasted. The series of questions makes it possible to make 10 potential diagnoses: 4 among neonates and 6 among older infants and children. Of course, an infant can present with multiple symptoms and more than one diagnosis is possible for any given child. The criteria for making each possible diagnosis are defined in Table 12.4.

Twenty-five percent of neonatal deaths were among low birth weight infants. This was determined either by birth weight being under 2,500 grams or by the mother reporting that her baby was very small in size. Twenty percent of neonatal deaths were reported by the mothers to have encountered difficult delivery. Seven percent of neonatal deaths were experienced by babies who suckled normally during the first two days of life, then had difficulty suckling during the illness that led to death and also suffered convulsions. The combination of symptoms are indicative of neonatal tetanus. These deaths also had the restriction of being among those that occurred between 4 and 30 days of birth. Cough and rapid or difficult breathing were experienced by 5 percent of neonates in the illness prior to death.

Possible diagnosis	Symptoms or criteria for diagnosis	Percentage of deaths
Age at death: <1 month (neonatal)		
Low birth weight	Birth weight <2500 grams or size at birth very small ¹	24.9
Obstetrical problems	Delivery by C section	1.3
	Difficult delivery ¹	19.2
	Difficult delivery and C-section	1.3
Neonatal tetanus	Death at 4-30 days and normal sucking first two days of life	34.4
	Death at 4-30 days and normal sucking first two days of life and difficulty sucking during illness before death	26.6
	Death at 4-30 days and normal sucking first two days of life and difficulty sucking during illness before death and convulsions ¹	6.6
Respiratory infection	Cough	4.5
	Cough and difficult/rapid breathing ¹	4.5
Number of deaths		74
Age at death: >1 month (postneonatal)		
Diarrhea	Diarrhea lasting more than 2 days	26.5
	Severe diarrhea lasting more than 2 days	18.2
	Diarrhea lasting more than 2 days and blood in stool	2.7
	Severe diarrhea lasting more than 2 days and blood in stool ¹	18.4
Respiratory infection	Cough and difficult/rapid breathing lasting more than 2 days ¹	30.2
Measles	Age at death above 4 months and skin rash lasting more than 3 days and fever lasting more than 3 days ¹	6.5
Malaria	Severe fever lasting more than 2 days ¹	0.3
Malnutrition	Extremely thin lasting 1 month or more	7.0
	Swelling of feet/legs lasting one month or more	1.2
	Extremely thin lasting 1 month or more or swelling of feet/legs lasting one month or more ¹	7.5
Dengue hemorrhagic fever	Bleeding nose/mouth/gums or black vomit/bloody stools ¹	10.9
Number of deaths		106

¹ Criteria selected for inclusion in algorithm for final diagnosis.

Episodes of diarrhea can range from mild to severe and in mild form is unlikely to result in dehydration and death. Thus death as a result of diarrhea must meet a more stringent criteria such that the diarrhea be severe, last more than two days, and include blood in the stool. This level of diarrhea was reported among 18 percent of deaths among infants and children 1 month or older. Indications of respiratory infection were experienced in 30 percent of these deaths, including cough lasting more than 2 days accompanied by difficult or rapid breathing. As with diarrhea, a skin rash can be symptomatic of numerous illnesses, not all of which are sufficient to cause death. Therefore the potential diagnosis of measles comes only after applying more stringent criteria than a skin rash. The 7 percent of non-neonatal deaths with potential for having been caused by measles are derived from infants who died after 4 months of age, had a skin rash lasting more than 3 days, accompanied by fever lasting more than 3 days. Eight percent of non-neonatal deaths may have been caused by malnutrition, the children having been extremely thin for more than one month or experiencing swelling of the feet or legs for more than a month. Symptoms of dengue fever are more distinctive than those of many other illnesses. Ten percent of non-neonatal deaths were reported among children who experienced bleeding from the nose, mouth, or gums or black vomit or bloody stools, indicative of dengue hemorrhagic fever.

Any one symptom or combination of symptoms can be consistent with multiple diagnoses. The factors responsible for the death of an infant may be multiple, thereby making it difficult to establish a single cause of death. In addition, the principle cause of death may be different from the symptoms witnessed just prior to death. It is not possible with these data to distinguish between the two. Table 12.5 shows the percent distribution of deaths among infants and children age 1 month or older for which a diagnosis has been made. The diagnosis was based on the criteria specified in Table 12.4, across all the symptoms that apply. For example, 35 percent of non-neonatal deaths due to diarrhea also meet only the criteria for diarrhea. However, 35 percent of postneonatal deaths due to diarrhea (as defined by meeting the criteria in Table 12.4) also meet the criteria for having respiratory infection. Twenty-three percent of non-neonatal deaths meeting the criteria for death due to diarrhea also meet the criteria for two or more other illnesses. Table 12.5 shows the difficulty in establishing one primary cause of death. The fact that the symptoms of dengue hemorrhagic fever are more specific than symptoms for many other illnesses is evidenced in the 73 percent of dengue cases defined by the algorithm in Table 12.4 meet only the criteria for dengue hemorrhagic fever, as shown in Table 12.5.

Table 12.5 Multiple diagnoses

Percent distribution of deaths among children age 1 month or older born since January 2002 that meet the criteria of diagnosis of diarrhea, respiratory infection, measles, malnutrition, and dengue hemorrhagic fever according to whether or not they also meet the criteria of diagnosis of one other specific disease or two or more diseases, Cambodia 2005

Diagnosis ¹	Diagnosis ¹						Total	Number of deaths
	Diarrhea	ARI	Measles	Malnutrition	Dengue hemorrhagic fever	Meet criteria of two or more other diseases ²		
Diarrhea	35.2 ^a	35.4	0.0	2.2	4.2	22.9	100.0	19
ARI	21.6	48.3 ^a	4.5	10.4	1.1	14.3	100.0	32
Measles	0.0	20.8	16.7 ^a	0.0	0.0	62.5	100.0	7
Malnutrition	5.5	41.7	0.0	47.8 ^a	0.0	5.0	100.0	8
Dengue hemorrhagic fever	7.1	2.9	0.0	0.0	72.4 ^a	17.6	100.0	12

¹ According to the final algorithm defined in Table 10.4

² Is also associated with two or more other diagnoses, for example, diarrhea symptoms also associated with respiratory infection and measles

^a Does not meet criteria of any other diagnosis

Ultimately, it would be useful to analyze the concordance between cause of death diagnosed via the algorithm of symptoms and mothers' reports. Then the next step would be to combine the two methods of assessing cause of death to make a final determination of potential cause of death. However, because of the small number of cases available, this chapter has focused on presenting the CDHS data on causes of death from mothers' reports. A design for an algorithm of symptoms was also presented.

This chapter presents findings on important areas of maternal health: antenatal, delivery, and postnatal care. This information, in combination with data on mortality, is useful in formulating programs and policies to improve maternal and child health services.

13.1 ANTENATAL CARE

The health care that a mother receives during pregnancy and at the time of delivery is important for the survival and well-being of both the mother and the child. Antenatal care (ANC) coverage is described according to the type of provider, number of ANC visits, stage of pregnancy at the time of the first and last visits, and services and information provided during ANC. It is also recommended that women receive two doses of tetanus toxoid vaccine, adequate amounts of iron and folic acid tablets, and iron syrup to prevent and treat anemia. Blood pressure checks and procedures to detect pregnancy complications are also part of ANC coverage. A well-designed and implemented ANC program facilitates detection and treatment of problems during pregnancy, such as anemia and infections, and provides an opportunity to disseminate health messages to women and their families.

Information on ANC coverage was obtained from women who had a birth in the five years preceding the survey. For women with two or more live births during the five-year period, data on antenatal care refer to the most recent birth only.

Source of Antenatal Care

Table 13.1 shows the percent distribution of mothers in the five years preceding the survey by source of antenatal care received during pregnancy. More than two in three (69 percent) women received ANC from trained personnel (doctors, nurses, and midwives) at least once. Sixty-one percent of women received care during pregnancy from midwives, 6 percent received care from a doctor, and 2 percent went to a nurse. More than one-fourth (28 percent) of women received no antenatal care for births in the preceding five years. The 2005 data show a significant increase in antenatal care compared with the 2000 CDHS, when only 38 percent of women had received antenatal care from a trained health professional. In 2000, more than half of women (55 percent) received no antenatal care.

Younger women are more likely to receive antenatal care from trained personnel, compared with older women. Mothers are more likely to receive care from a health professional for first births (80 percent) than for births of order six and higher (52 percent). There are differences in the use of antenatal care services between urban and rural women. Health professionals provided antenatal care for 79 percent of mothers in urban areas and 68 percent of mothers in rural areas. Additionally, in rural areas, 30 percent of women received no antenatal care at all, compared with 19 percent in urban areas.

Provincial differences in the source of antenatal care are significant: 92 percent of mothers in Svay Rieng received antenatal care from a health professional, compared with 28 percent of mothers in Mondol Kiri/Rattanak Kiri. The percentage of mothers who received no antenatal care is the highest in Mondol Kiri/Rattanak Kiri (66 percent) and the lowest in Svay Rieng and Pursat (8 percent). In Otdar Mean Chey, 23 percent of women received antenatal care from a traditional birth attendant.

Table 13.1 Antenatal care

Percent distribution of women who had a live birth in the five years preceding the survey by antenatal care (ANC) provider during pregnancy for the most recent birth, according to background characteristics, Cambodia 2005

Background characteristic	Doctor	Nurse	Midwife	Traditional birth attendant	Other	No one	Total	Number of women

Note: If more than one source of ANC was mentioned, only the provider with the highest qualifications is considered in this tabulation. Figures in parentheses are based on 25-49 unweighted cases.

na = Not applicable

The use of antenatal care services is strongly associated with the mother's level of education. Women with a secondary education or higher are more likely to receive antenatal care from any trained personnel (90 percent) than women with a primary education (71 percent) and women with no education (50 percent). Similarly, 46 percent of uneducated women receive no antenatal care, whereas the proportion of women who receive no care decreases to 27 percent and 9 percent for women with primary and secondary education or higher, respectively.

Antenatal care is more beneficial in preventing adverse pregnancy outcomes when it is sought early in the pregnancy and is continued throughout pregnancy. Health professionals recommend that the first antenatal visit should occur within the first three months of the pregnancy and continue on a monthly basis through week 28 of pregnancy and fortnightly up to week 36 (or until birth). If the first antenatal visit is made at the third month of pregnancy and as regularly as recommended, there will be a total of at least 12 to 13 antenatal visits. Table 13.2 shows that one-fourth of women (27 percent) make four or more antenatal care visits during their entire pregnancy. Table 13.2 includes antenatal care received from any type of provider listed in Table 13.1.

Twenty-three percent of women make their first antenatal care visit before the fourth month of pregnancy. The median duration of pregnancy for the first antenatal care visit is 4.2 months. This indicates that in Cambodia, women start antenatal care at a relatively late stage of their pregnancy.

Components of Antenatal Care

The effectiveness of antenatal checkups in ensuring safe motherhood depends in part on the tests and measurements done and the advice given during the checkups. The 2005 CDHS collected information on this important aspect of antenatal care by asking mothers who received antenatal checkups from all types of providers whether they received each of several components of ANC during their last pregnancy in the five years preceding the survey. Respondents were also asked whether they took iron tablets and intestinal parasite drugs during pregnancy. The results are shown in Table 13.3.

Sixty percent of mothers who received antenatal care reported that they were informed about pregnancy-related complications during their visits. Blood pressure was part of antenatal care for 81 percent of mothers. Urine and blood samples were taken from 24 and 18 percent of women, respectively. About two-thirds (63 percent) of women took iron tablets during pregnancy and 11 percent of women took intestinal parasite drugs.

Table 13.2 Number of antenatal care visits and timing of first visit

Percent distribution of women who had a live birth in the five years preceding the survey by number of antenatal care (ANC) visits for the most recent birth, and by the timing of the first visit, and among women with ANC, median months pregnant at first visit, according to residence, Cambodia 2005

¹ ANC includes visits with all provider types listed in Table 13.1.

Urban-rural differences exist for various components of antenatal care. Urban women are more likely to take iron and intestinal parasite drugs and about three times as likely to have blood and urine taken for testing. In Pursat, 90 percent of women were informed about signs of pregnancy complications, compared with 31 percent of women in Preah Vihear/Steung Treng and Mondol Kiri/Rattanak Kiri. Antenatal care content is also greatly affected by the level of mother's education. Women with secondary or higher education were far more likely to have received iron tablets (79 percent) than women with no education (47 percent).

Tetanus Toxoid Vaccinations

Tetanus toxoid injections are given to women during pregnancy to prevent deaths from neonatal tetanus. Neonatal tetanus can result when sterile procedures are not followed in cutting the umbilical cord after delivery. In the 2005 CDHS, information was collected on the number of doses of tetanus toxoid vaccine the mother received and on the source from which the tetanus toxoid vaccination was received for all births during the five-year period prior to the survey. In addition, questions were included to ascertain whether mothers received tetanus injections prior to the last birth to determine if the last birth was fully protected from neonatal tetanus.

Table 13.4 considers whether the last birth was fully protected against neonatal tetanus. An infant is considered to be fully protected if any of the following criteria are met: (1) the mother had two tetanus toxoid injections during the pregnancy; (2) the mother had a tetanus toxoid injection during the pregnancy plus an additional injection prior to the pregnancy; or (3) the mother did not have a tetanus toxoid injection during pregnancy but had at least five injections prior to the pregnancy. According to the 2005 CDHS results, about two-thirds of last-born children (69 percent) during the five-year period before the survey were fully protected against neonatal tetanus. There are provincial differences in the percentage of last-born children who were fully protected against neonatal tetanus. In Takeo, 88 percent of births were fully protected, compared with less than half of births in Mondol Kiri/Rattanak Kiri.

For more than half of births in the past five years (54 percent), the mother received two or more tetanus toxoid injections. The 2000 CDHS found that only 30 percent of women received two or more doses of tetanus toxoid vaccine.

Table 13.4 Tetanus toxoid injections

Percent distribution of women who had a live birth in the five years preceding the survey by number of tetanus toxoid injections (TTI) during last pregnancy and prior to the last live birth, and percentage of last live births protected against neonatal tetanus, according to background characteristics, Cambodia 2005

13.2 CHILDBIRTH AND DELIVERY

An important component of efforts to reduce the health risks of mothers and children is increasing the proportion of babies delivered under the supervision of health professionals. Proper medical attention and hygienic conditions during delivery can reduce the risk of complications and infections that may cause death or serious illness to either the mother or the baby or both. Data on delivery care was obtained for all births that occurred in the five years preceding the survey.

Place of Delivery

A large majority of births (78 percent) in the five years before the survey were delivered at home, with only 22 percent being delivered in a health facility (Table 13.5). The percentage of deliveries occurring in the home has declined, as the 2000 CDHS found that 89 percent of births in Cambodia occurred at home. Women are more likely to deliver their first birth at a health facility (31 percent), compared with higher birth orders. Children born in urban areas (50 percent) are three times more likely to be delivered in a health facility than children born in rural areas (17 percent). The proportion of births delivered in a health facility is twice as high in Phnom Penh (78 percent) as in the next highest province, Kandal (37 percent). There is also a strong association between the level of education of mothers and the place of delivery; the proportion of births delivered in a health facility is only 10 percent for uneducated mothers, compared with 48 percent for mothers with secondary and higher education.

Note: Total includes 20 women for whom information on number of antenatal care visits is not available.
¹ Includes only the most recent birth in the five years preceding the survey

Assistance at Delivery

Obstetric care by a trained provider during delivery is recognized as critical for the reduction of maternal and neonatal mortality. Table 13.6 shows the type of assistance during delivery by selected background characteristics. Forty-four percent of births are delivered with the assistance of a trained health professional, (i.e., a doctor, nurse, or midwife), an increase from 32 percent in 2000. Over half of births (55 percent) are delivered with the assistance of a traditional birth attendant (TBA). First births are more likely to be assisted by a trained health professional (54 percent) than subsequent births.

Table 13.6 Assistance during delivery

Percent distribution of live births in the five years preceding the survey by person providing assistance during delivery, and percentage delivered by caesarean-section, according to background characteristics, Cambodia 2005

Note: If the respondent mentioned more than one person attending during delivery, only the most qualified person is considered in this tabulation. Total includes 4 births for which information on place of delivery is not available.

Urban women are much more likely (70 percent) to receive assistance from a trained health professional during childbirth than rural women (39 percent). Conversely, rural women are more likely to receive assistance during birth from a traditional birth attendant (60 percent) than urban women (30 percent). In many provinces, the proportion of births assisted by a trained health professional is low. However, 86 percent of births in Phnom Penh and 74 percent of births in Kandal are assisted by a trained health professional. As expected, mother's education has a positive impact on delivery care. Births to women with primary education (43 percent) and secondary or higher education (80 percent) are more likely to receive delivery assistance from a health professional than births to women with no education (22 percent).

13.3 POSTNATAL CARE AND PRACTICES

Postnatal Care

A large proportion of maternal and neonatal deaths occurs during the first 48 hours after delivery. Safe motherhood programs have recently increased their emphasis on the importance of postnatal care, recommending that all women receive a health checkup within two days of delivery. To assess the extent of postnatal care utilization, respondents who gave birth in the five years preceding the survey were asked whether they had received a health check after the delivery of their last birth. Table 13.7 shows the timing of the first postnatal checkup for women who had a birth in the past five years.

Thirty percent of women received no postnatal care. Sixty-four percent of mothers received postnatal care within the crucial first two days of delivery, with 32 percent receiving care within four hours of delivery. Urban women are more likely to receive postnatal care (74 percent) than rural women during the first two days after delivery (62 percent). Women with secondary or higher education (82 percent) are more likely to receive postnatal care within two days of delivery than women with either no education (55 percent) or only primary education (62 percent). More than one-third of women (37 percent) who did not deliver in a health facility did not receive a postnatal check-up.

Table 13.7 Timing of first postnatal checkup

Among women giving birth in the five years preceding the survey, the percent distribution of the mother's first postnatal checkup for the last live birth by time after delivery, according to background characteristics, Cambodia 2005

Table 13.8 presents information on the provider of postnatal care for women who delivered in the five years preceding the survey. Forty-one percent of women received postnatal care from a health professional (midwife, doctor, or nurse), and 29 percent of women received postnatal care from traditional birth attendants. Health professionals are twice as likely to provide postnatal care to mothers in urban rather than rural areas (66 percent versus 37 percent). Similarly, mothers with secondary and higher education (76 percent) are much more likely to receive postnatal care from a trained health professional than women with either no education (20 percent) or only primary education (39 percent).

Table 13.8 Type of provider of first postnatal checkup

Among women giving birth in the five years preceding the survey, the percent distribution by type of provider of the mother's first postnatal health check for the last live birth, according to background characteristics, Cambodia 2005

13.4 PERCEIVED PROBLEMS IN ACCESSING WOMEN'S HEALTH CARE

Many different factors can prevent women from getting medical advice or treatment for themselves. In the 2005 CDHS, women were asked about various problems they face in accessing health care. Table 13.9 shows that 89 percent of women reported having one or more problems in accessing health care for themselves.

Table 13.9 Problems in accessing health care

Percentage of women who reported that they have serious problems in accessing health care for themselves when they are sick, by type of problem, according to background characteristics, Cambodia 2005

Background characteristic	Problems in accessing health care									Number of women
	Getting permission to go for treatment	Getting money needed for treatment	Distance to health facility	Having to take transport	Not wanting to go alone	Concern no female provider available	Concern no provider available	Concern no drugs available	At least one problem accessing health care

Note: Total includes 16 women for whom information on compensation for employment is not available.

The main problem in accessing health care was not having money for treatment (74 percent). Half of women were concerned that there would be no drugs or no health provider available at the health facility. Forty-five percent of women reported that they did not want to go alone to the health facility. Women in the 15-19 year age group cited problems in getting permission to go to a health facility (29 percent) and not wanting to go to the facility alone (66 percent). As expected, rural women were twice as likely to have problems related to distance to the health facility and need for transportation as urban women. Women with no education were more likely to have problems related to lack of money for treatment.

This chapter presents findings on several areas of importance to child health: characteristics of the neonate (birth weight and size at birth), vaccination status of children, and important childhood illnesses and their treatment. The information on birth weight and birth size is important for the design and implementation of programs aimed at reducing neonatal and infant mortality. Many of the deaths in early childhood can be prevented by immunizing children against preventable diseases and by ensuring that children receive prompt and appropriate treatment when they become ill.

14.1 CHILD'S SIZE AT BIRTH

Birth weight is a major determinant of infant and child health and mortality. Children whose birth weight is less than 2.5 kilograms, or children reported to be 'very small' or 'smaller than average' are considered to have a higher than average risk of early childhood death. For births in the five years preceding the survey, birth weight was recorded in the questionnaire if available from either a written record or the mother's recall. Because birth weight may not be known for many babies, the mother's estimate of the baby's size at birth was also obtained. Even though it is subjective, it can be a useful proxy for the weight of the child. Table 14.1 presents information on child's size at birth according to background characteristics.

Table 14.1 shows that 40 percent of babies were weighed at birth, which represents a significant increase since the 2000 CDHS when only 17 percent of babies were reported to have been weighed at birth. Among those births for which the mother was able to report the baby's weight, 8 percent were classified as low birth weight; i.e., they weighed less than 2.5 kilograms at birth. A higher proportion of first-born children (11 percent) and children of birth order six and higher (10 percent) are of low birth weight when compared with children of birth orders two through five (5 to 7 percent). Children born to mothers who smoke are of low birth weight (11 percent) in greater proportion than children born to mothers who do not smoke (8 percent). The proportion of births born of low birth weight does vary across provinces (from 4 to 14 percent); however, the proportions with a reported birth weight varies drastically, from a low of 18 percent in Preah Vihear/Steung Treng and Mondol Kiri/Rattanak Kiri to a high of 90 percent in Phnom Penh.

Table 14.1 also includes information on the mother's assessment of the baby's size at birth. In the absence of birth weight a mother's subjective assessment of the size of the baby at birth may be useful. However, this assessment may vary among respondents because it is based on the mother's own perception of what is small, average, or large for a baby and not on a uniform definition. Eighty-five percent of births were considered by their mothers to be of average or larger than average size. Eleven percent were perceived as smaller than average, and 4 percent were considered very small.

Table 14.1 Child's weight and size at birth

Percent distribution of live births in the five years preceding the survey with a reported birth weight by birth weight; percentage of all births with a reported birth weight and percent distribution of all live births in the five years preceding the survey by mother's estimate of baby's size at birth, according to background characteristics, Cambodia 2005

² Mother's current use

14.2 IMMUNIZATION OF CHILDREN

Universal immunization of children against six vaccine-preventable diseases (namely, tuberculosis, diphtheria, whooping cough, tetanus, polio, and measles) is crucial to reducing infant and child mortality. Data on differences in vaccination coverage among subgroups of the population are of great assistance for program planning. Additionally, information on immunization coverage is important for the monitoring and evaluation of the Expanded Programs on Immunization (EPI).

The 2005 CDHS collected information on vaccination coverage for all living children born in the five years preceding the survey. Guidelines developed by the World Health Organization define children to be fully vaccinated when they have received a vaccination against tuberculosis (BCG), three doses each of the DPT and polio vaccines, and a measles vaccination by the age of 12 months. BCG should be given at birth or at first clinical contact; DPT and polio require three vaccinations at approximately 4, 8, and 12 weeks of age. Measles should be given at or soon after reaching 9 months of age.

Information on vaccination coverage was collected in two ways: from vaccination cards shown to the interviewer and from mothers' verbal reports. If the cards were available, the interviewer copied the vaccination dates directly onto the questionnaire. When there was no vaccination card for the child or if a vaccine had not been recorded on the card as being given, the respondent was asked to recall the vaccines given to her child. The top three rows of Table 14.2 show the percentage of children age 12-23 months who have received the various vaccinations by source of information, that is, from vaccination card or mother's report.

Table 14.2 Vaccinations by source of information

Percentage of children age 12-23 months who received specific vaccines at any time before the survey, by source of information (vaccination card or mother's report), and percentage vaccinated by 12 months of age, Cambodia 2005

Source of information	BCG	DPT			Polio ¹				Measles	All basic vaccinations ²	No vaccinations	Number of children
		1	2	3	0	1	2	3				
Vaccinated at any time before the survey												
Vaccination card	65.9	66.3	64.4	61.3	5.0	66.2	64.5	59.8	56.3	52.7	0.2	1,012
Mother's report	25.5	24.3	20.7	17.0	3.2	24.4	21.2	17.1	20.6	13.9	6.8	505
Either source	91.4	90.6	85.1	78.3	8.2	90.6	85.7	76.9	76.9	66.6	7.0	1,517
Vaccinated by 12 months of age³												
	91.0	89.7	83.7	75.5	8.2	89.8	84.4	74.2	70.2	59.9	7.6	1,517

¹ Polio 0 is the polio vaccination given at birth.

² BCG, measles, and three doses each of DPT and polio vaccine (excluding polio vaccine given at birth)

³ For children whose information was based on the mother's report, the proportion of vaccinations given during the first year of life was assumed to be the same as for children with a written record of vaccination.

The last row of Table 14.2 shows that 60 percent of children age 12-23 months were fully vaccinated by 12 months of age. Nearly all children had received the BCG vaccination (91 percent) and 70 percent had been vaccinated against measles. Because DPT and polio vaccines are often administered at the same time, their coverage rates are similar. Ninety percent of children received the first doses of DPT and of polio, and three-fourths received the third doses. This is primarily due to the success of the national immunization day campaigns during which polio vaccines are administered.

Table 14.3 shows vaccination coverage among children age 12-23 months by background characteristics. This information may give some indication of the success of the immunization program in reaching out to all population subgroups. There are no significant differences in vaccination coverage between males and females. While there is no significant difference between children in urban and rural areas, there are substantial differences in coverage across provinces. The percentage of children fully vaccinated is lowest in the provinces of Mondol Kiri/Rattanak Kiri

(35 percent), Kampot/Krong Kep (41 percent), and Siem Reap (43 percent). The provinces with the highest proportion of children fully vaccinated are Battambang/Krong Pailin (82 percent), Kampong Speu (81 percent), and Phnom Penh (81 percent).

The percentage of children fully vaccinated increases substantially with mother's educational level. Children of mothers with secondary or higher education are much more likely to be fully vaccinated (83 percent) than children whose mothers have no education (52 percent). The percentage of children fully vaccinated also increases according to the wealth of the household; children living in the wealthiest households are more likely to be fully vaccinated (76 percent) than children from the poorest households (56 percent).

Table 14.3 Vaccinations by background characteristics

¹ Polio 0 is the polio vaccination given at birth.

² BCG, measles, and three doses each of DPT and polio vaccine (excluding polio vaccine given at birth)

Trends in Vaccination Coverage

Trends in vaccination coverage can be seen by comparing similarly collected data in the 2000 CDHS with the data from the 2005 CDHS. The data show that vaccination coverage in Cambodia has significantly improved over the past five years. Figure 14.1 shows the percentage of children age 12-23 months who were fully vaccinated by 12 months of age has doubled from 31 percent in 2000 to 60 percent in 2005.

Figure 14.1 Trends in Vaccination by 12 Months of Age (among Children 12-23 Months)

Note: All includes BCG, measles, and three doses each of DPT and polio vaccine (excludes polio 0 vaccine given at birth).

14.3 ACUTE RESPIRATORY INFECTION

Acute respiratory infection (ARI) is a leading cause of childhood morbidity and mortality throughout the world. Early diagnosis and treatment with antibiotics can prevent a large proportion of deaths caused by ARI. In the 2005 CDHS, the prevalence of ARI was estimated by asking mothers whether their children under age five had been ill with a cough accompanied by short, rapid breathing in the two weeks preceding the survey. These symptoms are compatible with ARI. It should be noted that the morbidity data collected are subjective—they are based on the mother's perception of illness with no validation from medical personnel—and that the prevalence of ARI is subject to seasonality.

Table 14.4 shows the percent of children under five with symptoms of ARI during the two weeks preceding the survey according to selected background characteristics. Nine percent of children under five years of age showed symptoms of ARI at some time in the two weeks preceding the survey. With the exception of those under six months of age, prevalence of ARI decreases with increasing age of the child. Children age 6-11 and 12-23 months experience the symptoms of ARI (11 percent) in higher proportions than other age groups.

The proportion of children with ARI symptoms decreases steadily with increasing wealth quintile of the household, from a high of 12 percent among children living in households of the lowest wealth quintile to a low of 3 percent among children living in households of the highest wealth quintile. There are significant provincial variations in the prevalence of ARI, ranging from a low of 2 percent in Phnom Penh and Kampot/Krong Kep to a high of 26 percent in Otdar Mean Chey experiencing the symptoms of ARI.

Table 14.4 Prevalence and treatment of symptoms of ARI

Among children under age five, the percentage who had symptoms of acute respiratory infection (ARI) in the two weeks preceding the survey and among children with symptoms of ARI, the percentage who received specific treatments, according to background characteristics, Cambodia 2005

Note: Figures in parentheses are based on 25-49 unweighted cases. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.

¹ Symptoms of ARI (cough accompanied by short, rapid breathing which was chest-related) is considered a proxy for pneumonia.

² Excludes pharmacy, shop, and traditional practitioner

³ Includes grass, shrubs, crop residues

About half (48 percent) of all children under five with cough and rapid breathing were taken to a health facility or provider to seek treatment or advice. Children of mothers with secondary or higher level education are more likely to receive treatment for symptoms of ARI (62 percent) than those of mothers with no schooling (44 percent) or only primary schooling (48 percent).

14.4 FEVER

The 2005 CDHS also asked mothers about fever, which is a primary manifestation of malaria and other acute infections in children. Malaria and fever can contribute to high levels of malnutrition and mortality. Malaria is discussed in greater detail in Chapter 16.

Table 14.5 shows the percent of children under five who had a fever during the two weeks preceding the survey according to selected background characteristics. Overall, 35 percent of children under five years of age had a fever at some time in the two weeks preceding the survey. The prevalence of fever varies by age of child. As with ARI, children age 6-11 months and 12-23 months are more commonly sick with fever (46 and 42 percent, respectively) than other children. There are no significant variations in the prevalence of fever by sex of the child. Similarly, there is little notable difference in the prevalence of fever between children in urban and rural areas.

Provincial variations, however, are significant; prevalence of fever ranges from a low of 12 percent in Krong Preah Sihanouk/Kaoh Kong to a high of 54 percent in Kampong Thom and 53 percent in Preah Vihear/Steung Treng. Mother's education has little impact on the prevalence of fever among children less than five years old.

Slightly less than half (43 percent) of all children under five with fever were taken to a health facility or provider to seek treatment or advice. Children of mothers with secondary or higher level education are more likely to receive treatment for fever (50 percent) than those of mothers with no schooling (39 percent) or only primary schooling (42 percent). The proportion of children for whom treatment was sought from a health facility or provider is highest in Takeo (69 percent) and Svay Rieng (65 percent) and lowest in Kampong Speu (25 percent) and Kampong Thom (28 percent).

Less than 1 percent of children with fever received anti-malarial drugs while 12 percent received antibiotic drugs. Use of antibiotic drugs is more common in rural areas (13 percent) than in urban areas (8 percent) and is twice as common among mothers with at least a secondary education (16 percent) than mothers with no education (9 percent). The highest use of antibiotic drugs to treat fever is in Kandal (28 percent) and Battambang/Krong Pailin (26 percent) provinces.

Table 14.5 Prevalence and treatment of fever

Among children under age five, the percentage who had a fever in the two weeks preceding the survey; and among children with fever, the percentage of children for whom treatment was sought from a health facility or provider, the percentage who took antimalarial drugs, and the percentage who took antibiotic drugs, by background characteristics, Cambodia 2005

14.5 DIARRHEA

Dehydration caused by severe diarrhea is a major cause of morbidity and mortality among young children although the condition can be easily treated with oral rehydration therapy (ORT). Exposure to diarrhea-causing agents is frequently related to the use of contaminated water and to unhygienic practices in food preparation and disposal of excreta.

Table 14.6 shows the percentage of children under five with diarrhea in the two weeks preceding the survey, according to selected background characteristics. Overall, 20 percent of all children under five had diarrhea while 3 percent had diarrhea with blood.

The occurrence of diarrhea varies by age of the child. As with ARI and fever, young children age 6-11 and 12-23 months are more prone to diarrhea than children in the other age groups (32 percent and 28 percent, respectively). Diarrhea is slightly more common among rural children (20 percent) than urban children (16 percent). There are also variations in the prevalence of diarrhea by province. Children living in Kampong Cham are more susceptible to episodes of diarrhea (30 percent) than children living in other provinces. Children living in Krong Preah Sihanouk/Kaoh Kong and Svay Rieng have the lowest prevalence of diarrhea (9 and 10 percent, respectively) when compared with children living in other provinces. The prevalence of diarrhea with blood follows a pattern similar to that observed for diarrhea in general.

The 2005 CDHS asked mothers of children under age five who had diarrhea what was done to treat the illness. Table 14.7 shows the percentage of children with diarrhea who received specific treatments according to background characteristics. Thirty-seven percent of children with diarrhea were taken to a health provider. Nearly one in two children (44 percent) of mothers with some secondary or higher education were taken to a health provider, compared with 35 percent of children of mothers with no schooling. Notable differences also exist by place of residence. The proportion of children in rural areas taken to a health facility is 38 percent whereas only 28 percent of children in urban areas were taken to a health provider. There are also variations across provinces; nearly two-thirds of children living in Takeo were taken to a health provider in contrast to less than one in ten children living in Krong Preah Sihanouk/Kaoh Kong.

Table 14.6 Prevalence of diarrhea

Note: ORT includes solution prepared from oral rehydration salts(ORS), prepackaged ORS packet, and recommended home fluids (RHF). Figures in parentheses are based on 25-49 unweighted cases.

¹ Excludes pharmacy, shop, and traditional practitioner

Comparable data from the 2000 CDHS show a higher percentage of children with diarrhea were taken to a health provider in 2005 than in 2000 (37 percent versus 22 percent).

Fifty-eight percent of children with diarrhea were treated with some kind of oral rehydration therapy (ORT): 21 percent were treated with a solution prepared from an ORS packet, 21 percent were given recommended home fluids, and 38 percent were given increased fluids. However, about one in five children (18 percent) with diarrhea did not receive any treatment at all.

Diarrhea treatment varies by age: 71 percent of children age 12-23 months received ORT compared with 27 percent of children under six months of age. Children who had diarrhea with blood are more likely to receive ORT than others. There are also slight differences between urban and rural areas; 59 percent of children in rural areas received ORT or increased fluids compared with 51 percent of children in urban areas. Children living in Phnom Penh (30 percent) and Siem Reap (34 percent) are least likely to receive ORT or increased fluids.

14.6 FEEDING PRACTICES

Mothers are normally encouraged to continue feeding children with diarrhea and to increase the amount of fluids. These practices help to reduce dehydration and minimize the adverse consequences of diarrhea on the child's nutritional status. Mothers were asked whether they gave the child less, the same amount, or more fluids and food than usual when their child had diarrhea. Table 14.8 shows the percent distribution of children under five who had diarrhea in the two weeks preceding the survey by feeding practices, according to background characteristics.

Thirty-nine percent of children who had diarrhea were given the same amount of liquid as usual and 38 percent were given more. Thirteen percent of children were given somewhat less than the usual amount, and 4 percent were given much less than the usual amount. Four percent of children who had diarrhea were given no liquids.

Regarding the amount of food offered to children who had diarrhea, 45 percent were given the same as usual, 12 percent were given more than usual, 27 percent were given somewhat less than the usual amount of food, 5 percent were given much less than the usual amount of food, and 9 percent did not receive food during their illness.

Children under age 6 months and children residing in Svay Rieng, Mondol Kiri/Rattanak Kiri, and Otdar Mean Chey are the least likely to receive at least the same amount of liquid or more during episodes of diarrhea than other children. Regarding the amount of food offered during diarrhea, children under age 6 months, children with bloody diarrhea, and children residing in Banteay Mean Chey, Kampong Thom, and Kampot/Krong Kep are the least likely to receive at least the same amount of food or more.

Table 14.8 Feeding practices during diarrhea

Percent distribution of children under age five who had diarrhea in the two weeks preceding the survey by amount of liquids and food offered compared with normal practice, by background characteristics, Cambodia 2005

Note: Figures in parentheses are based on 25-49 unweighted cases.

14.7 KNOWLEDGE OF ORS PACKETS

A simple and effective response to dehydration caused by diarrhea is a prompt increase in the child's fluid intake through some form of oral rehydration therapy, which may include the use of a solution prepared from packets of oral rehydration salts (ORS). To ascertain how widespread knowledge of ORS is in Cambodia, respondents were asked whether they know about ORS packets. Interviewers displayed a sample ORS packet to respondents when asking the question.

Table 14.9 shows that almost all (91 percent) of women who gave birth in the five years preceding the survey know about ORS packets. This represents a large increase over the past 5 years; in the 2000 CDHS, 50 percent of women reported knowing about ORS packets.

Mothers with no education are less likely to know about ORS packets (85 percent) than with primary schooling (92 percent) or secondary or higher schooling (98 percent). Knowledge of ORS also varies by province, as only half of mothers in Mondol Kiri/Rattanak Kiri know about ORS packets.

14.8 STOOL DISPOSAL

If human feces are left uncontained, disease may spread by direct contact or by animal contact with the feces. Hence, the proper disposal of children's stools is extremely important in preventing the spread of disease. Table 14.10 presents information on the disposal of the stools of children under age five, by background characteristics.

Forty percent of children's stools are left uncontained: 5 percent are put or rinsed into a drain or ditch, 8 percent are thrown into the garbage, and 27 percent are left in the open. Fifty-eight percent of children's stools are disposed of hygienically: 42 percent are buried in the yard and 10 percent are disposed of in a toilet or latrine. Additionally, 6 percent of children under five use a toilet or latrine.

There are pronounced differences in practices of stool disposal by mother's level of education and type of toilet facilities available. For more than three-fourths of the children (77 percent) of mothers with secondary and higher education, stools are disposed of hygienically (child uses toilet, child's stool thrown in toilet, or buried in yard), compared with 46 percent of children of mothers with no education. Similarly, 86 percent of children in households with improved toilets that are not shared with other households have their stools contained, compared with 52 percent of children in the households using non-improved or shared toilet facilities.

Table 14.9 Knowledge of ORS packets or pre-packaged liquids

Percentage of mothers who gave birth in the five years preceding the survey who know about ORS packets or pre-packaged liquids for treatment of diarrhea, by background characteristics, Cambodia 2005

ORS = Oral rehydration salts

Children's stools are more likely to be contained in urban areas (73 percent) than in rural areas (56 percent). Of course, toilet facilities are more available in urban areas. There are also large provincial variations in practices of stool disposal. For example, the percentage of children whose stools are contained in disposal ranges from a low of 13 percent in Mondol Kiri/Rattanak Kiri to a high of 88 percent in Otdar Mean Chey.

Table 14.10 Disposal of children's stools

Percent distribution of mothers whose youngest child under age five is living with her by the manner of disposing of the child's fecal matter, according to background characteristics, Cambodia 2005

This chapter covers nutritional concerns for children and women. The section on children covers the following related topics: anthropometric assessment of the nutritional status of children under five years of age; infant and young child feeding practices, including breastfeeding and feeding with solid/semisolid foods; diversity of foods fed; frequency of feeding; and micronutrient status, supplementation, and fortification. The section on women covers: nutritional status of women 15 to 49 years of age; the diversity of foods eaten by mothers of children under three years; and micronutrient status, supplementation and fortification.

Adequate nutrition is critical to child development. The period from birth to two years of age is important to optimal growth, health, and development. This period is one marked for growth faltering, micronutrient deficiencies, and common childhood illnesses, such as diarrhea and acute respiratory infections (ARI). Optimal feeding practices reported in this chapter include early initiation of breastfeeding, exclusive breastfeeding during the first six months of life, continued breastfeeding for up to two years of age and beyond, timely introduction of complementary feeding at six months of age, frequency of feeding solid/semisolid foods, and the diversity of food groups fed to children between 6 and 23 months of age. A summary indicator that describes the quality of infant and young child (age 6-23 months) feeding practices (IYCF) is included.

A woman's nutritional status has important implications for her health as well as the health of her children. Malnutrition in women results in reduced productivity, an increased susceptibility to infections, retarded recovery from illness, and heightened risks of adverse pregnancy outcomes. A woman, who has poor nutritional status as indicated by a low body mass index (BMI), short stature, anemia, or other micronutrient deficiency, has a greater risk of obstructed labor, of having a baby with a low birth weight, of producing lower quality breast milk, of mortality due to postpartum hemorrhage, and of morbidity of both herself and her baby.

15.1 NUTRITIONAL STATUS OF CHILDREN

The 2005 CDHS collected data on the nutritional status of children under five years of age from a 50 percent subsample of households selected for the CDHS. Data were collected with the aim of calculating three indices—namely, weight-for-age, height-for-age, and weight-for-height—all of which take age and sex into consideration. Weight measurements were taken using a lightweight electronic SECA scale designed and manufactured under the guidance of UNICEF. The scale allowed for the weighing of very young children through an automatic mother-child adjustment that eliminated the mother's weight while she was standing on the scale with her baby. Height measurements were carried out using a measuring board produced by Shorr Productions. Children younger than 24 months were measured lying down (recumbent length) on the board, while standing height was measured for older children.

As recommended by WHO, the anthropometric measurements of children in the survey were compared with an international reference population defined by the U.S. National Center for Health Statistics (NCHS) and accepted by the U.S. Centers for Disease Control and Prevention (CDC). Each of the three nutritional status indicators described below is expressed in standard deviation units from the mean of the reference population.¹ The use of this reference population is based on the finding that well-nourished young children in all population groups (for which data exist) follow very similar growth patterns and thus exhibit similar distributions of height and weight at given ages (Martorell

¹ The distribution of the standard reference population has been normalized and hence the mean and median coincide.

and Habicht, 1986). The reference populations are useful for comparison, facilitating the examination of differences in the anthropometric status of subgroups in a population and changes in nutritional status over time. In any large population, there is variation in height and weight; this variation approximates a normal distribution.

Each of these indices—height-for-age, weight-for-height, and weight-for-age—provides different information about growth and body composition, which is used to assess nutritional status. The height-for-age index is an indicator of linear growth retardation and cumulative growth deficits. Children whose height-for-age Z-score is below minus two standard deviations (-2 SD) from the mean of the reference population are considered short for their age (stunted) and are chronically malnourished. Children who are below minus three standard deviations (-3 SD) from the mean of the reference population are considered severely stunted. Stunting reflects failure to receive adequate nutrition over a long period of time and is also affected by recurrent and chronic illness. Height-for-age, therefore, represents the long-term effects of malnutrition in a population and does not vary according to recent dietary intake.

The weight-for-height index measures body mass in relation to body length and describes current nutritional status. Children whose Z-scores are below minus two standard deviations (-2 SD) from the mean of the reference population are considered thin (wasted) for their height and are acutely malnourished. Wasting represents the failure to receive adequate nutrition in the period immediately preceding the survey and may be the result of inadequate food intake or a recent episode of illness causing loss of weight and the onset of malnutrition. Children whose weight-for-height is below minus three standard deviations (-3 SD) from the mean of the reference population are considered severely wasted.

Weight-for-age is a composite index of height-for-age and weight-for-height. It takes into account both acute and chronic malnutrition. Children whose weight-for-age is below minus two standard deviations from the mean of the reference population are classified as underweight. Children whose weight-for-age is below minus three standard deviations (-3 SD) from the mean of the reference population are considered severely underweight.

Thirty-seven percent of children under five are stunted and 13 percent are severely stunted. Seven percent of children under five are wasted, and 36 percent are underweight.

Table 15.1 and Figure 15.1 indicate that stunting is apparent even among children less than 6 months of age (6 percent). Stunting increases with the age of the child; this is evidenced by the increase in stunting from 9 percent among children age 6-8 months to 49 percent among children age 18-23 months. There is very little difference in the level of stunting by gender. Stunting is highest if the birth interval is less than 24 months (47 percent). Size at birth is an important indicator of the nutritional status of children. Half of the children who were reported to have been very small at birth were stunted. Children whose biological mothers were not in the household are more likely to be stunted (43 percent) than children whose mothers were interviewed (37 percent). A larger percentage (41 percent) of children whose mothers were underweight were stunted than children of normal weight mothers (36 percent). More rural children are stunted (38 percent) than urban children (31 percent). Regional variation in nutritional status of children is substantial with stunting being highest in Pursat province (62 percent) and lowest in Phnom Penh province (22 percent). With increasing wealth quintile and increasing level of mother's education the proportion of children stunted goes down.

Table 15.1 Nutritional status of children

Percentage of children under five years classified as malnourished according to three anthropometric indices of nutritional status: height-for-age, weight-for-height, and weight-for-age, by background characteristics, Cambodia 2005

Middle	11.6	36.5	-1.6	0.3	5.5	-0.8	5.0	33.5	-1.6	681
Fourth	9.7	35.5	-1.5	1.1	6.0	-0.8	5.5	34.3	-1.6	633
Highest	5.6	19.4	-1.1	0.7	6.7	-0.6	2.8	23.1	-1.2	605
Total	12.9	37.3	-1.6	0.8	7.3	-0.8	6.9	35.6	-1.6	3,587

Note: Table is based on children who stayed in the household the night before the interview. Each of the indices is expressed in standard deviation units (SD) from the median of the NCHS/CDC/WHO International Reference Population. Table is based on children with valid dates of birth (month and year) and valid measurement of both height and weight. Total includes 27 cases for which size at birth is missing and 34 cases for which mother's nutritional status is missing.

¹ Includes children who are below -3 standard deviations (SD) from the International Reference Population median

² Excludes children whose mothers were not interviewed

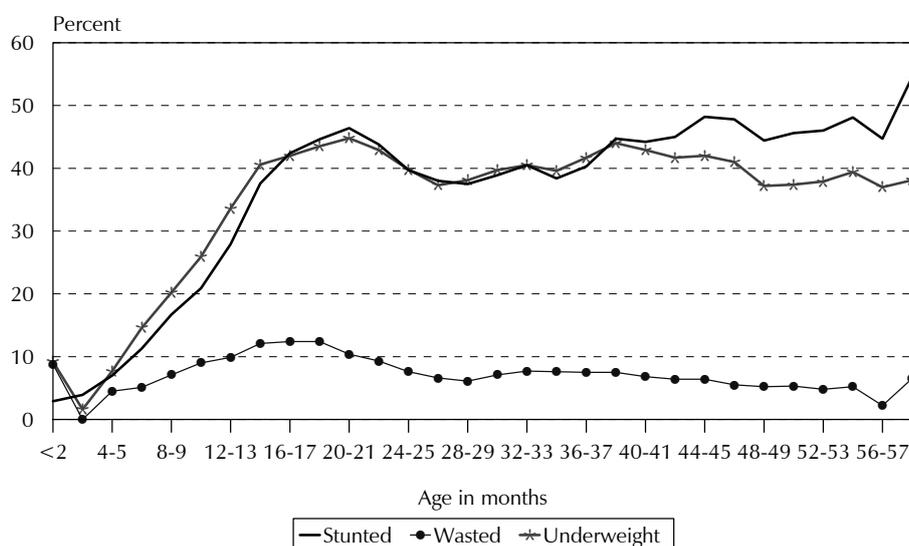

³ First-born twins (triplets, etc.) are counted as first births because they do not have a previous birth interval.

⁴ Includes children whose mothers are deceased

⁵ Mother's nutritional status in terms of BMI (Body Mass Index) is presented in Table 15.10.

⁶ For women who are not interviewed, information is taken from the Household Questionnaire. Excludes children whose mothers are not listed in the Household Questionnaire

Figure 15.1 Nutritional Status of Children by Age

Note: Stunting reflects chronic malnutrition; wasting reflects acute malnutrition; underweight reflects chronic or acute malnutrition or a combination of both.

CDHS 2005

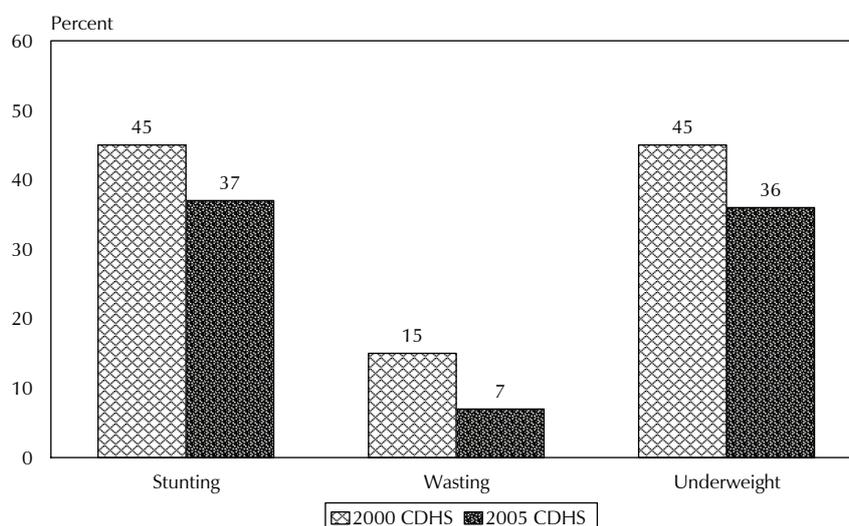

The prevalence of wasting is higher than the national average among children age 9-23 months. The proportion of wasting in children of underweight (BMI<18.5) mothers is almost twice that of children whose mothers have normal BMI. Wasting is highest in Pursat (17 percent) 10 percentage points higher than the national average. Wasting declines steadily with increasing education of the mother and wealth quintile.

Figure 15.1 shows that the percentage of children underweight increases sharply from 5 percent among children under age 6 months doubles to 10 percent among children age 6-8 months, increases seven times among children age 9-11 months then peaks at 45 percent among children age 18-23 months with small decreases thereafter. This may be due to inappropriate and/or inadequate feeding practices because increasing levels of children underweight by age coincides with the age at which normal complementary feeding starts. Half of the provinces listed in Table 15.1 have percentages of underweight children above the national average (36 percent).

Trends in Children’s Nutritional Status

Data from the 2005 CDHS can be compared with similarly collected data from the 2000 CDHS (Figure 15.2). A comparison of the data shows that there have been some improvements in the nutritional status of children in the past five years. The percentage of children stunted fell by 8 percentage points from 45 percent in 2000 to 37 percent in 2005. Similarly, the percentage of children wasted declined by 8 percentage points from 15 percent in 2000 to 7 percent in 2005 and underweight declined by 9 percentage points from 45 percent in 2000 to 36 percent in 2005.

Figure 15.2 Trends in Nutritional Status of Children under Five Years

Note: *Stunting* reflects chronic malnutrition; *wasting* reflects acute malnutrition; *underweight* reflects chronic or acute malnutrition or a combination of both.

15.2 INITIATION OF BREASTFEEDING

Early initiation of breastfeeding is encouraged for a number of reasons. Mothers benefit from early suckling because it stimulates breast milk production and facilitates the release of oxytocin, which helps the contraction of the uterus and reduces postpartum blood loss. The first breast milk contains colostrum, which is highly nutritious and has antibodies that protect the newborn from diseases. Early initiation of breastfeeding also fosters bonding between mother and child.

Table 15.2 Initial breastfeeding						
Percentage of children born in the five years preceding the survey who were ever breastfed, and for the last-born children born in the five years preceding the survey ever breastfed, the percentage who started breastfeeding within one hour and within one day of birth and the percentage who received a prelacteal feed, by background characteristics, Cambodia 2005

Total	96.8	7,789	35.1	68.3	55.7	5,711

Note: Table is based on births in the past five years whether the children are living or dead at the time of interview. Figures in parentheses are based on 25-49 unweighted cases.

¹ Includes children who started breastfeeding within one hour of birth

² Children given something other than breast milk during the first three days of life

³ Doctor, nurse, or midwife

Table 15.2 shows the percentage of all children born in the five years before the survey by breastfeeding status and the timing of initial breastfeeding, by background characteristics. Breastfeeding is nearly universal in Cambodia, with 97 percent of children born in the five years preceding the survey having been breastfed at some time. The proportion of children ever breastfed ranges from a low of 92 percent in Phnom Penh to a high of 98 percent in Kampong Thom, Pursat,

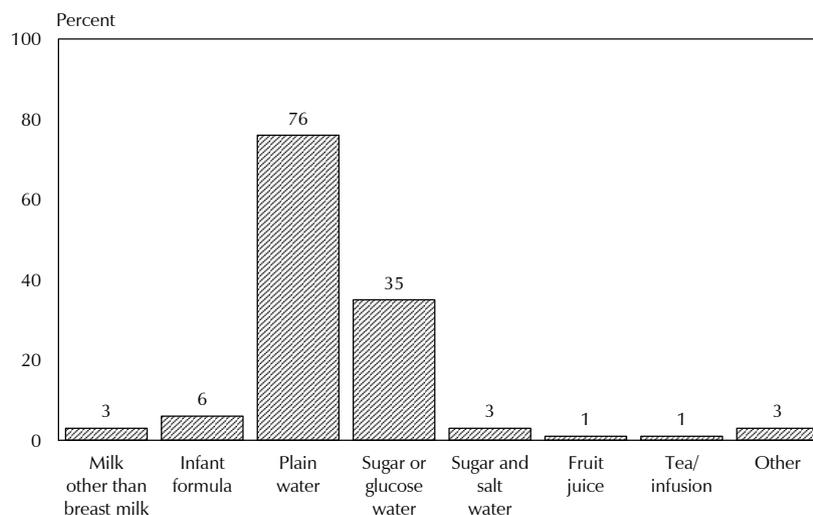

and Svay Rieng. However, the percentage of children ever breastfed does not vary much by other background characteristics.

About one in three children is breastfed within one hour of birth (35 percent) and 68 percent within one day of birth. Fifty-six percent of children were given a prelacteal feed, that is, something other than breast milk during the first three days of life.

There is a small difference in the timing of initial breastfeeding by gender of the child; a larger percentage of females are breastfed within one hour and one day than are males. Other background characteristics have important influences on early breastfeeding practices. Early initiation of breastfeeding is more common among children whose mothers were assisted at delivery by a health professional than among children delivered at home. Regional differences are evident in the initial breastfeeding practices. Children born in Pursat are over five times more likely to be breastfed within one hour of birth than children born in Kampong Cham and Kampong Chhnang. Highly educated mothers are more likely than those with little or no education to put their newborn to the breast within the first hour or day of birth. The percentage of children who were put to the breast early increases as wealth increases. Differences in early breastfeeding by wealth are small.

Figure 15.3 presents the various kinds of prelacteal liquids given to the Cambodian children in 2005 CDHS. Cambodian children receive plain water (76 percent) and sugar or glucose water (35 percent) as the most common type of prelacteal liquids.

Figure 15.3 Among Last-born Children Born in the Five Years Preceding the Survey Who Ever Received a Prelacteal Liquid, the Percentage Who Received Various Types of Liquids

CDHS 2005

15.3 BREASTFEEDING STATUS BY AGE

UNICEF and WHO recommend that children be exclusively breastfed during the first 6 months of life and that children be given solid or semisolid complementary food in addition to continued breastfeeding from six months on. Exclusive breastfeeding is recommended because breast milk is uncontaminated and contains all the nutrients necessary for children in the first few months of life. In addition, the mother's antibodies in breast milk provide immunity to disease. Early supplementation is discouraged for several reasons. First, it exposes infants to pathogens and increases their risk of infection, especially disease. Second, it decreases infants' intake of breast milk and therefore suckling, which reduces breast milk production. Third, in a harsh socioeconomic environment, supplementary food is often nutritionally inferior.

Information on complementary feeding was obtained by asking mothers about the current breastfeeding status of all children under five years of age and, for the youngest child born in the three-year period before the survey and living with the mother, food (liquids or solids) given to the child the day before the survey.

Table 15.3 Breastfeeding status by age

Percent distribution of youngest children under three years living with their mother by breastfeeding status and the percentage currently breastfeeding; and the percentage of all children under three years using a bottle with a nipple, according to age in months, Cambodia 2005

Age in months	Percent distribution of youngest children under three living with their mother by breastfeeding status							Percentage currently breastfeeding	Number of youngest children under three years	Percentage using a bottle with a nipple ¹	Number of children under three years
	Breastfeeding and consuming:						Total				
	Not breast-feeding	Exclusively breastfed	Plain water only	Non-milk liquids/juice	Other milk	Complementary foods

Note: Breastfeeding status refers to a 24-hour period (yesterday and the past night). Children who are classified as *breastfeeding and consuming plain water only* consumed no liquid or solid supplements. The categories of not breastfeeding, exclusively breastfed, breastfeeding and consuming plain water, non-milk liquids/juice, other milk, and complementary foods (solids and semisolids) are hierarchical and mutually exclusive, and their percentages add to 100 percent. Thus children who receive breast milk and non-milk liquids and who do not receive complementary foods are classified in the non-milk liquid category even though they may also get plain water. Any children who get complementary food are classified in that category as long as they are breastfeeding as well.

¹ Based on all children under three years

Table 15.3 shows the percent distribution of youngest children under three years living with the mother by breastfeeding status and percentage of children under three years using a bottle with a nipple, according to age in months. The data presented in Table 15.3 and Figure 15.3 shows that not all children under 6 months are exclusively breastfed. Contrary to WHO's recommendations less than half of Cambodian children age 4-5 months is exclusively breastfed. The table also shows that about three-fourths of children under 2 months of age are exclusively breastfed, 18 percent consume breast milk and plain water, and 6 percent are consuming other milk in addition to breast milk. Although, 2005 CDHS results indicate that 80 percent of children start eating complementary foods by 6 months, still 6 percent of children continue to be exclusively breastfed and 10 percent receive just plain water in addition to breast milk.

More than half of Cambodian children continue to breastfeed until the age of two years (Figure 15.4). Exclusive breastfeeding quickly declines from birth to age 6-7 months. However, a few infants are still exclusively breastfed beyond this age which is not recommended. Although other liquids are not needed before six months, over 20 percent of infants are given water from birth.

Figure 15.4 Infant Feeding Practices by Age

CDHS 2005

15.4 DURATION AND FREQUENCY OF BREASTFEEDING

Table 15.4 shows the median duration of breastfeeding by selected background characteristics. The estimates of median and mean durations of breastfeeding are based on current status data, that is, the proportion of last-born children in the three years preceding the survey who were being breastfed at the time of the survey.

The median duration of breastfeeding is 21.0 months, while the mean duration is 21.6 months. There is little difference in the duration of breastfeeding by sex of the child. Rural children are breastfed for a slightly longer duration than urban children. Highly educated mothers breastfeed their children for a shorter duration than mothers with little or no education. Mothers from the highest wealth quintile breastfeeds for the shortest duration.

Both duration and frequency of breastfeeding can affect the length of postpartum amenorrhea. Table 15.4 shows that the overwhelming majority (97 percent) of children under six months of age were breastfed 6 or more times in the 24 hours preceding the survey. In line with expectations, breastfeeding is slightly more frequent in the daytime than at night, with the mean number of feeds in the daytime being 5.9 compared with 5.2 at night. Breastfeeding during the day is most frequent among children residing in the Pursat than in the other provinces, while night feeds are most frequent among children in Kampong Thom and Prey Veng province.

Table 15.4 Median duration and frequency of breastfeeding

Median duration of any breastfeeding, exclusive breastfeeding, and predominant breastfeeding among children born in the three years preceding the survey, percentage of breastfeeding children under six months of age living with the mother who were breastfed six or more times in the 24 hours preceding the survey, and mean number of feeds (day/night), by background characteristics, Cambodia 2005

Background characteristic	Median duration (months) of breastfeeding among last-born children in the past three years ¹				Frequency of breastfeeding among children under six months of age ²

Note: Median and mean durations are based on current status. Includes children living and deceased at the time of the survey. Figures in parentheses are based on 25-49 unweighted cases.

¹ It is assumed that non-last-born children and last-born children not currently living with the mother are not currently breastfeeding

² Excludes children who do not have a valid answer on the number of times breastfed

³ Either exclusively breastfed or received breast milk and plain water, and/or non-milk liquids only

na = Not applicable

15.5 TYPES OF COMPLEMENTARY FOODS

UNICEF and WHO recommend the introduction of solid food to infants around the age of 6 months because by that age breast milk alone is no longer sufficient to maintain a child's optimal growth. In the transition to eating the family diet, children from the age of six months are fed small quantities of solid and semisolid foods throughout the day. During this transition period (ages 6-23 months), the prevalence of malnutrition increases substantially in many countries because of increased infections and poor feeding practices.

Table 15.5 provides information on the types of food given to the youngest child under three years of age living with the mother on the day and night preceding the survey, according to their breastfeeding status. The data show that among breastfeeding infants very few receive infant formula or any other kinds of milk. However, 5 percent of younger breastfeeding infants (2-3 months) are already consuming food made from grains, and 3 percent consume food made from meat, fish, poultry, and eggs.

Table 15.5 Foods and liquids consumed by children in the day or night preceding the interview

Percentage of youngest children under three years of age living with the mother who consumed specific types of foods in the day or night preceding the interview, by breastfeeding status and age, Cambodia 2005

Age in months	Liquids			Solid or semisolid foods										Number of children
	Infant formula	Other milk ¹	Other liquids ²	Fortified baby foods	Food made from grains ³	Fruits and vegetables rich in vitamin A ⁴	Other fruits and vegetables	Food made from roots and tubers	Food made from beans, peas, or nuts	Meat, fish, and poultry, eggs	Any other solid or semisolid food	Food made with oil, fat, or butter	Sugary foods

Note: Breastfeeding status and food consumed refer to a 24-hour period (yesterday and the past night). An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.

¹ Other milk includes fresh, tinned, and powdered animal milk

² Does not include plain water

³ Includes fortified baby food

⁴ Includes pumpkin, orange or yellow squash, carrots, sweet potatoes, dark green leafy vegetables, mangoes, and papayas

Between the ages of 6 and 23 months, the consumption of foods made from grains is the highest among both breastfeeding (92 percent) and nonbreastfeeding (97 percent) children, compared with the consumption of other types of solid or semisolid foods. More than half of all the children age 6-23 months have eaten a food rich in vitamin A in the day or night preceding the survey. There is a low consumption of food made from roots or tubers and food made from beans, peas, or nuts.

Comparing dietary intake of children by their breastfeeding status, a higher proportion of solid and semisolid foods are being consumed by nonbreastfeeding children. However, few are receiving infant formula (21 percent) or other milks (14 percent) in addition to solid foods which is essential since they are not benefiting from breast milk. A larger percentage of non-breastfed children age 6-23 months are receiving meat, fish, poultry and eggs (96 percent) compared with breastfed children (80 percent) in this same age group.

15.6 INFANT AND YOUNG CHILD FEEDING (IYCF) PRACTICES

Appropriate infant and young child feeding (IYCF) practices include timely initiation of feeding solid/semisolid foods from age six months and increasing the amount and variety of foods and frequency of feeding as the child gets older, while maintaining frequent breastfeeding. Guidelines have been established with respect to IYCF practices for children age 6-23 months (PAHO/WHO, 2003 and WHO, 2005).

Table 15.6 presents a summary indicator of IYCF practices. The indicator takes into account the percentages of children for whom feeding practices met minimum standards with respect to food diversity (i.e., the number of food groups consumed) and feeding frequency (i.e., the number of times the child was fed), as well the consumption of breast milk or other milks or milk products. Breastfed children are considered as being fed with the minimum standards if they consume at least three food groups² and receive foods other than breast milk at least twice per day in the case of infants 6-8 months and at least three times per day in the case of children 9-23 months. Nonbreastfed children are considered to be fed if they consumed milk or milk products, four food groups (including milk products), and are fed at least four times per day.

According to the results presented in Table 15.6, 87 percent of youngest children age 6-23 months living with the mother received breast milk or other milk or milk products during the 24-hour period before the survey, 63 percent had a minimally diverse diet (i.e., they had been fed foods from the minimum number of food groups depending on their age and breastfeeding status), and 67 percent had been fed the minimum number of times appropriate for their age. Feeding practices for about half of Cambodian children age 6-23 months met the minimum standard with respect to all three of these feeding practices (Figure 15.5).

² Food groups used in the assessment of minimum standard of feeding practices include: milk other than breast milk, foods made from grains, roots, and tubers; fruits and vegetables rich in vitamin A; other fruits and vegetables; eggs; meat, poultry, fish, and shellfish (and organ meats); beans, peas, and nuts; and foods made with oil, fat, or butter.

Table 15.6 Infant and young child feeding (IYCF) practices

Percentage of youngest children age 6-23 months living with their mother who are fed according to three IYCF feeding practices based upon number of food groups and times they are fed during the day or night preceding the survey by breastfeeding status and background characteristics, Cambodia 2005

Background characteristic	Among breastfed children 6-23 months, percentage fed:				Among nonbreastfed children 6-23 months, percentage fed:					Among all children 6-23 months, percentage fed:				
	3+ food groups ¹	Minimum times or more ²	Both 3+ food groups and minimum times or more	Number of children	Milk or milk products ³	4+ food groups	4+ times or more	With 3 IYCF practices ⁴	Number of children	Breast-milk or milk products ³	3+ or 4+ food groups ⁵	Minimum times or more ⁶	With all 3 IYCF practices	Number of children

Note: Figures in parentheses are based on 25-49 unweighted cases. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.

¹ Food groups: a. infant formula, milk other than breast milk or other milk products; b. foods made from grains, roots, and tubers, including porridge, fortified baby food from grains; c. fruits and vegetables rich in vitamin A; d. other fruits and vegetables; e. eggs; f. meat, poultry, fish, and shellfish (and organ meats); g. legumes and nuts; h. foods made with oil, fat, butter.

² At least twice a day for breastfed infants 6-8 months and at least three times a day for breastfed children 9-23 months

³ Includes commercial infant formula, fresh, tinned and powdered animal milk, yogurt, and other milk products

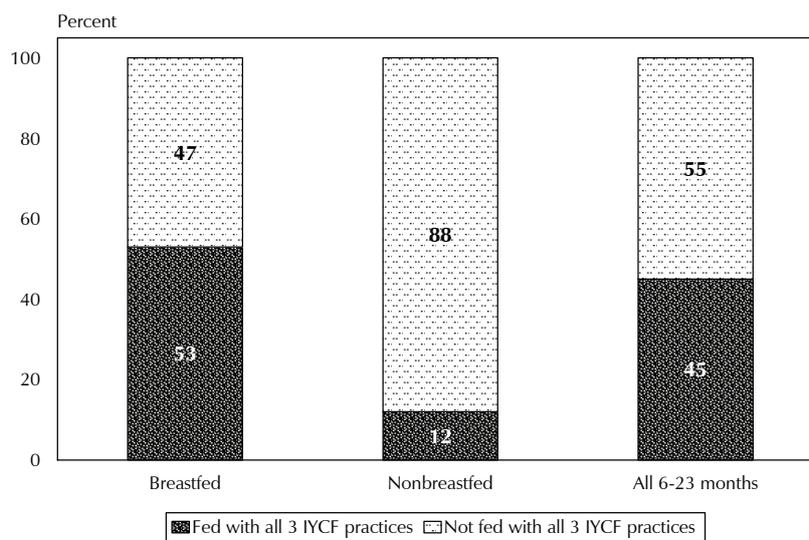

⁴ Nonbreastfed children ages 6-23 months are considered to be fed with three appropriate feeding practices if they receive other milk or milk products and are fed at least the minimum number of times per day with at least the minimum number of food groups.

⁵ 3+ food groups for breastfed children and 4+ food groups for non-breastfed children

⁶ Fed solid or semisolid food at least twice a day for infants 6-8 months, 3+ times for other breastfed children, and 4+ times for non-breastfed children

Breastfed children were slightly more likely to be fed the minimum number of times and slightly less likely to receive foods from the minimum number of groups than nonbreastfed children. As the child's age increased, feeding practices were generally more likely to comply with minimum standards for the breastfed child and less likely to comply for the non-breastfed child. Regional differences in the feeding practices of children are apparent in the 2005 CDHS results, children residing in Kandal province are twice likely to be fed according to the three IYCF practices compared with Banteay Mean Chey. Variations in feeding practices with the other characteristics shown in Table 15.6 are generally minor.

Figure 15.5 Infant and Young Child Feeding (IYCF) Practices

CDHS 2005

15.7 PREVALENCE OF ANEMIA IN CHILDREN

Common causes of anemia include inadequate intake of iron, folate, vitamin B₁₂ or other nutrients. Anemia can also result from thalassemia, sickle cell disease, malaria, and intestinal worm infestation. Anemia may be the underlying cause of maternal mortality, spontaneous abortion, premature birth, and low birth weight. Iron and folic acid supplementation and antimalarial prophylaxis for pregnant women, promotion of the use of insecticide-treated bednets by pregnant women and children under five, and six-month deworming for children are some of the important measures to reduce anemia prevalence among vulnerable groups. Anemia is characterized by a low level of hemoglobin in the blood.

Table 15.7 shows the percentage of children age 6-59 months classified as having anemia, by background characteristics. Anemia is a critical public health problem in Cambodia, where more than half (62 percent) of Cambodian children 6-59 months old are anemic, with 29 percent mildly anemic, 32 percent moderately anemic, and 1 percent severely anemic. Anemia is highest among children age 9-11 months, and children who live in Pursat province. A higher percentage of children of uneducated mothers have anemia. The percentage of children with anemia decreases as wealth quintile increases.

¹ Includes children whose mothers are deceased

² For women who are not interviewed, information is taken from the Household Questionnaire. Excludes children whose mothers are not listed in the Household Questionnaire.

Figure 15.6 presents the trends in anemia status among children age 6-59 months. The level of total and various gradation of anemia have remained about the same in last five years.

Figure 15.6 Trends in Anemia Status among Children Age 6-59 Months

15.8 MICRONUTRIENT INTAKE AMONG CHILDREN

A serious contributor to childhood morbidity and mortality is micronutrient deficiency. Children can receive micronutrients from foods, food fortification, and direct supplementation. Table 15.8 looks at measures relating to intake of several key micronutrients among children.

Vitamin A is an essential micronutrient for the immune system and plays an important role in maintaining the epithelial tissue in the body. Severe vitamin A deficiency (VAD) can cause eye damage. VAD can also increase severity of infections such as measles and diarrheal diseases in children and slows recovery from illness. Vitamin A is found in breast milk, other milks, liver, eggs, fish, butter, red palm oil, mangoes, papayas, carrots, pumpkins, and dark green leafy vegetables. The liver can store an adequate amount of the vitamin for four to six months. Periodic dosing (usually every six months) of vitamin A supplements is one method of ensuring that children at risk do not develop VAD.

The CDHS collected information on the consumption of foods rich in vitamin A and on the coverage of supplements. Table 15.8 shows that 88 percent of last-born children living with the mother consumed foods rich in vitamin A in the 24-hour period before the survey. Consumption of foods rich in vitamin A increases from 43 percent among children age 6-8 months to 98 percent among children age 18-23 months. There is no gender difference in the consumption of foods rich in vitamin A. Not surprisingly, breastfeeding children are much less likely to consume foods rich in vitamin A than nonbreastfeeding children. Children living in Battambang/Krong Pailin, Kratie, Kampot/Krong Kep, and Kandal are more likely than children living in other provinces to consume foods rich in vitamin A.

Eighty-seven percent of children consume foods rich in iron. Noticeable differences by background characteristics similar to those seen for the consumption of foods rich in vitamin A.

Table 15.8 Micronutrient intake among children

Percentage of youngest children age 6-35 months living with their mother who consumed foods rich in vitamin A and iron in the day or night preceding the survey, and percentage of children age 6-59 months who received vitamin A supplements in the six months preceding the survey, who received iron supplements in the past seven days, who received deworming medication in the six months preceding the survey, and who live in households using iodized salt, by background characteristics, Cambodia 2005

Total	88.3	87.3	3,338	34.5	1.2	26.7	6,527	73.5	6,432

Note: Information on vitamin A and iron supplements and deworming medication is based on the mother's recall.

na = Not applicable

¹ Includes meat (and organ meat), fish, poultry, eggs, pumpkin, orange or yellow squash, carrots, sweet potatoes, dark green leafy vegetables, mango, and papaya

² Includes meat, (including organ meat), fish, poultry, and eggs

³ Deworming for intestinal parasites is commonly done for helminthes and for schistosomiasis.

⁴ Excludes children in households in which salt was not tested

Only one in three children age 6-59 months received a vitamin A supplement in the six months before the survey. Differences in the consumption of vitamin A supplements by gender, area of residence, mother's age at birth, and wealth quintile are small. The difference by breastfeeding status is marked, with a higher proportion of breastfeeding children receiving vitamin A supplements. Children residing in Kampong Cham are least likely to receive vitamin A supplements compared with children in the other regions.

Inadequate amounts of iodine in the diet are related to serious health risks for young children. The 2005 CDHS results show that 74 percent of children 6-59 months live in households using iodized salt. Children living in Battambang/Krong Pailin, Phnom Penh, Pursat, and Kratie are more likely to live in households using iodized salt.

15.9 USE OF IODIZED SALT

Iodine is an important micronutrient. Dietary deficiency of iodine constitutes a major, global public health concern. A lack of sufficient iodine is known to cause goiter, cretinism (a severe form of neurological defect), spontaneous abortion, premature birth, infertility, stillbirth, and increased child mortality. Iodine deficiency disorder (IDD) is the single most common cause of preventable mental retardation and brain damage in the world.

In the 2005 CDHS, a rapid test was used to determine the presence or absence of iodine in the salt used for cooking in the household. The test kit consisted of ampoules of a stabilized starch solution and a weak acid-based solution. A drop of the starch solution was squeezed onto a salt sample obtained in the household. A change in color indicated the presence of iodine.

Table 15.9 shows the percentage of households using iodized salt. Overall, 73 percent of households had salt with some iodine. A higher percentage of urban households (85 percent) are using iodized salt compared with rural households (71 percent). In Prey Veng, Svay Rieng, and Kampot/Krong Kep provinces less than 50 percent of households are using iodized salt.

15.10 NUTRITIONAL STATUS OF WOMEN

The height and weight of women age 15-49 was measured among a 50 percent subsample of households selected in the CDHS. The data are used to derive a measure of adult nutritional status known as body mass index (BMI). In this report, two indicators of nutritional status are presented: height and body mass index (BMI).

The height of a woman is associated with past socioeconomic status and nutrition during childhood and adolescence. A woman's height is used to predict the risk of difficulty in delivery because small stature is often associated with small pelvis size and the potential for obstructed labor. The risk of giving birth to a low birth weight baby is influenced by the mother's nutritional status. The cutoff point for the height at which mothers can be considered at risk varies between populations but normally falls between 140 and 150 centimeters. As in other DHS surveys, a cutoff point of 145 cm is used for the 2005 CDHS.

The index used to measure thinness or obesity is known as the body mass index (BMI), or the Quetelet index. BMI is defined as weight in kilograms divided by height squared in meters (kg/m^2). A cutoff point of 18.5 is used to define thinness or acute undernutrition and a BMI of 25 or above usually indicates overweight or obesity.

Table 15.10 presents the mean values of the two indicators of nutritional status and the proportions of women falling into high-risk categories, according to background characteristics. Women for whom there was no information on height and/or weight and for whom a BMI could not be estimated are excluded from this analysis. The data analysis on BMI is based on 7,799 women, while the height analysis is based on 8,370 women age 15-49 years. Overall, 8 percent of women are shorter than 145 cm. There are small differences in the height of women by background characteristics. A larger percentage of women in the Mondol Kiri/Rattanak, Kampong Thom and Otdar Mean Chey provinces are below 145 cm than women in the other provinces. As expected, women with less or no education and in the lowest wealth quintile are more likely to be below 145 cm.

Table 15.10 shows that there are large differentials across background characteristics in the percentage of women assessed as undernourished (BMI less than 18.5) or "thin" and overweight (BMI 25 or higher). Twenty percent of women were found to be underweight (BMI less than 18.5), while 10 percent were overweight or obese. Women in the age group of 15-19 are the thinnest compared with other age groups. More women have a BMI less than 18.5 in rural areas (21 percent) than in urban areas (17 percent). However, as expected the percentage of overweight or obese women is higher in urban areas (14 percent) than in rural areas (9 percent). Kampong Thom (25 percent), Prey Veng (27 percent), and Takeo (25 percent) have the highest percentage of undernourished women and Banteay Mean Chey has the lowest percentage (14 percent). The percentage of overweight or obese women in the highest wealth quintile is almost four times compared with the lowest quintile.

Compared with the 2000 CDHS the proportion of undernourished women in the reproductive age group has remained the same; however, the rate of overnutrition (BMI \geq 25.0) has gone up by 4 percentage points (Figure 15.7).

Table 15.10 Nutritional status of women

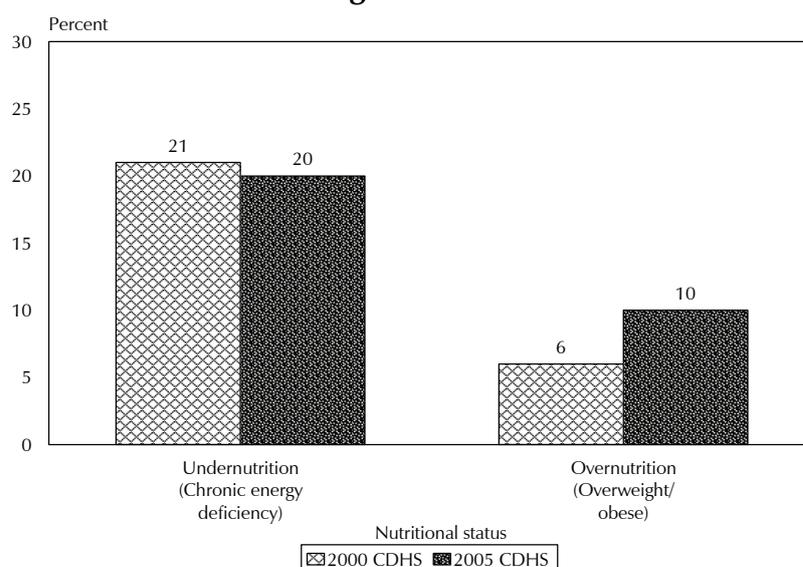

Among women age 15-49, the percentage with height under 145 cm, mean body mass index (BMI), and the percentage with specific BMI levels, by background characteristics, Cambodia 2005

Background characteristic	Height		Mean Body Mass Index (BMI)	Body Mass Index ¹							Number of women
	Percent-age below 145 cm	Number of women		Normal	Thin			Overweight/obese			
				18.5-24.9 (total normal)	<18.5 (total thin)	17.0-18.4 (mildly thin)	<17.0 (moderately and severely thin)	≥25.0 (total overweight/obese)	25.0-29.9 (overweight)	≥30.0 (obese)

15.11 FOODS CONSUMED BY MOTHERS

The quality and quantity of food that mothers consume influences their health and that of their children, especially the health of breastfeeding children. The 2005 CDHS included questions on the type of foods consumed by mothers of children under age three during the day and night preceding the interview.

Table 15.11 shows that the staple diet of mothers of young children in Cambodia consists of foods made from grains (99 percent), and meat, fish, shellfish, poultry, and eggs (98 percent). Three out of four women consume fruits and vegetables rich in vitamin A. Smaller proportions of mothers consume milk or other milk products (6 percent) and foods made from beans, peas, or nuts (13 percent). Only 11 percent of mothers drink tea or coffee and 31 percent consume foods made with oil, fat or butter or sugary foods.

Table 15.11 Foods consumed by mothers in the day or night preceding the interview

Among mothers age 15-49 with a child under age three years living with them, the percentage who consumed specific types of foods in the day or night preceding the interview, by background characteristics, Cambodia 2005

15.12 PREVALENCE OF ANEMIA IN WOMEN

Table 15.12 shows the prevalence of anemia among women age 15-49. With 47 percent of women having anemia, it is a critical public health problem in Cambodia with 35 percent mildly anemic, 10 percent moderately anemic and just 1 percent severely anemic. Women with high parity, with little or no education, are pregnant, and living in poor households has higher prevalence of anemia. Anemia is also higher among rural than urban women. Women residing in Phnom Penh have the lowest prevalence of anemia (29 percent) compared with the other provinces.

Table 15.12 Prevalence of anemia in women

Percentage of women age 15-49 with anemia, by background characteristics, Cambodia 2005

Figure 15.8 indicates compared with 2000 CDHS the prevalence of total anemia and mild anemia has gone down by nine percentage points in 2005 CDHS. However, there has been little or no change in the rates of moderate and severe anemia.

**Figure 15.8 Trends in Anemia Status among Women
Age 15-49**

15.13 MICRONUTRIENT INTAKE AMONG MOTHERS

Adequate micronutrient intake by women has important benefits for both women and their children. Breastfeeding children benefit from micronutrient supplementation that mothers receive, especially vitamin A. Iron supplementation of women during pregnancy protects mother and infant against anemia. It is estimated that one-fifth of perinatal mortality and one-tenth of maternal mortality are attributable to iron deficiency anemia. Anemia also results in an increased risk of premature delivery and low birth weight. Finally, iodine deficiency is also related to a number of adverse pregnancy outcomes.

Table 15.13 includes a number of measures that are useful in assessing the extent to which women are receiving adequate intake of vitamin A, iron during pregnancy, and iodine. The first indicators focused on the percentages of women with children under age three who reported that they consumed foods rich in vitamin A and iron during the 24-hour period prior to the DHS. The results indicate that 99 percent mothers of young children consumed vitamin A-rich fruits and vegetables and 98 percent mothers consumed iron-rich foods (i.e., meat, poultry, fish and eggs) in the 24 hours preceding the survey. In general the consumption of vitamin A and iron rich foods is high in Cambodian women with children and it does not vary much by background characteristics.

Table 15.13 also looks at the extent to which women receive vitamin A supplements following delivery. Only 27 percent of women reported that they had received a capsule in the two-month period following the delivery of their last-born child. With regard to iron supplementation during pregnancy, more than half of women who gave birth during the five-year period before the 2005 CDHS reported that they had taken iron tablets or syrup during the pregnancy preceding their last live birth. Among women reporting that they took supplements, the majority said that they took the supplements for less than 60 days. Percentage of women who took iron supplements varies by province and educational status of women.

As was the case among children, more than seven in ten women live in households in which the salt used in cooking was tested and found to be adequately iodized.

Table 15.13. Micronutrient intake among mothers

Among women age 15-49 with a child under three years living with them, the percentage who consumed foods rich in vitamin A and iron in the 24 hours preceding the survey; the percentage of women with a child born in the past five years who received a vitamin A dose in the first two months after the birth of the last child; the percentage of mothers who during the pregnancy of the last child born in the five years prior to the survey suffered from night blindness, the percentage who took iron tablets or syrup for specific numbers of days, and the percentage who took deworming medication; and the percentage of women with a child born in the past five years who live in households using iodized salt, by background characteristics, Cambodia 2005

Background characteristic	Consumption of foods rich in vitamin A and iron in the 24 hours preceding the survey among women with a child under three years				For the last child born in the past 5 years										
	Percentage consumed foods rich in vitamin A ¹	Percentage consumed foods rich in iron ²	Number of women with a child under 3 years	Percentage of women who received vitamin A dose post-partum ³	Percentage of women who suffered night blindness during pregnancy		Number of days women took iron tablets or syrup during pregnancy				Percentage of women who took deworming medication during pregnancy ⁵	Number of women with a child born in the past 5 years	Percentage of women in households using iodized salt ⁶	Number of women in households with salt tested

⁴ Women who reported night blindness but did not report difficulty with vision during the day

⁵ Deworming for intestinal parasites is commonly done for helminthes and for schistosomiasis

⁶ Excludes women in households where salt was not tested

16.1 INTRODUCTION

Malaria is a serious public health problem in Cambodia. In 2005, there were over 60,000 reported malaria cases. (Department of Planning and Health Information, 2005). The majority of malaria cases are caused by the *plasmodium falciparum* species of the malaria parasite, and a high level of drug resistance has been documented. However, people are not at equal risk of contracting malaria. Some areas of the country are virtually malaria-free, while other areas are malaria endemic. Thus, the country is divided into malaria-risk zones, ranging from low to high risk, and some areas of the country are not in malaria zones at all. The CDHS collected malaria data from all households included in the survey, including areas of both low and high risk of malaria and areas both within and outside the malaria risk zones.

Cambodia promotes the use of insecticide-treated nets (ITNs) to prevent malaria infection. With the assistance of the Global Fund for AIDS, Tuberculosis and Malaria, long-lasting insecticide treated nets (LLINs) are being distributed in remote rural areas free of charge and distributed in cities and towns through social marketing (WHO and UNICEF, 2005). In addition, hammock nets and retreatment tablets are socially marketed through the private sector to mobile workers in the forest areas. People living in forested areas are at highest risk of contracting malaria.

16.2 MALARIA PREVENTION

Ownership of Mosquito Nets

The use of ITNs is a major component of the malaria prevention strategy in Cambodia. During the CDHS 2005 survey, information was collected on the ownership and use of mosquito nets, both treated and untreated.

Coverage of mosquito nets is high in Cambodia, as shown in Table 16.1. Nationwide, 96 percent of households own at least one mosquito net. This high coverage is an increase since 2000 when 82 percent of households reported having a mosquito net (CDHS, 2000). Two-thirds of households own more than one. The vast majority of these nets are not treated with insecticide. Only 10 percent of households own a net that is pretreated or a nonpretreated net that has been treated with insecticide at any time. One in 20 households owns an insecticide-treated mosquito net, that is, a factory-treated net that does not require any further treatment, a pretreated net bought within the past 12 months, or a net that has been soaked in insecticide in the past 12 months.

The distribution of ever-treated nets and ITNs varies greatly by province. The percentage of households owning an ever-treated net exceeds 50 percent in Kratie, Otdar Mean Chey, Preah Vihear/Steung Treng, and Mondol Kiri/Rattanak Kiri. These same provinces have the highest ownership of ITNs as well. Nearly half of households in Preah Vihear/Steung Treng own at least one ITN.

Ownership of at least one mosquito net increases slightly with the wealth quintile of the household. Ownership of more than one mosquito net rises steadily with wealth quintile from 44 percent in the lowest wealth quintile to 86 percent in the highest wealth quintile. However, the percentage of households that own at least one ever-treated net or own an ITN declines with increasing wealth quintile and is highest among the poorest households. For example, among households in the highest wealth quintile, only 3 percent own at least one ever-treated net as compared with 18 percent of households in the lowest wealth quintile.

Table 16.1 Household possession of mosquito nets

Percentage of households with at least one and more than one mosquito net (treated or untreated), ever-treated mosquito net, and insecticide-treated net (ITN), and the average number of nets of each type per household, by background characteristics, Cambodia 2005

Background characteristic	Any type of mosquito net			Ever-treated mosquito net ¹			Insecticide-treated mosquito net ² (ITNs)			Number of households
	Percentage with at least one	Percentage with more than one	Average number of nets per household	Percentage with at least one	Percentage with more than one	Average number of ever-treated nets per household	Percentage with at least one	Percentage with more than one	Average number of ITNs per household

¹ An ever-treated net is a pretreated net or a non-pretreated net which has subsequently been soaked with insecticide at any time.

² An insecticide-treated net (ITN) is 1) a factory-treated net that does not require any further treatment, or 2) a pretreated net obtained within the past 12 months, or 3) a net that has been soaked with insecticide within the past 12 months.

Use of Mosquito Nets by Children

Children under five years of age are especially vulnerable to malaria. Table 16.2 presents information on the percentage of children under age five who slept under a mosquito net (treated or untreated) the night before the survey. Overall, nearly nine in ten children (88 percent) slept under a net the night prior to the survey, while only 9 percent slept under an ever-treated net and 4 percent slept under an ITN the night prior to the survey.

Table 16.2 Use of mosquito nets by children

Percentage of children under five years of age who slept under a mosquito net (treated or untreated), an ever-treated mosquito net, or an insecticide-treated net (ITN) the night before the interview, by background characteristics, Cambodia 2005

Total	88.2	9.3	4.2	7,178

¹ An ever-treated net is a pretreated net or a non-pretreated net which has subsequently been soaked with insecticide at any time.

² An insecticide-treated net (ITN) is 1) a factory-treated net that does not require any further treatment, or 2) a pretreated net obtained within the past 12 months, or 3) a net that has been soaked with insecticide within the past 12 months.

Little variation exists in the use of nets by age or sex of children. Children in rural areas are more likely to sleep under a mosquito net than urban children. The data for use of nets show similar regional trends to net ownership. Six in ten children in Preah Vihear/Steung Treng and Mondol Kiri/Rattanak Kiri slept under an ever-treated net on the night before the interview, as did half of children in Otdar Mean Chey. With respect to ITNs, the provinces with the highest use are, once again, Preah Vihear/Steung Treng, Mondol Kiri/Rattanak Kiri, and Otdar Mean Chey (34 percent, 31 percent, and 28 percent, respectively).

Use of Mosquito Nets by Women

As in the case of children under five years of age, pregnant women are especially susceptible to malaria. Table 16.3 shows the percentage of all women and pregnant women who slept under any mosquito net and the proportion who slept under an ever-treated net or ITN the night prior to the interview, by background characteristics. Generally, 85 percent of all women and 86 percent of pregnant women slept under a mosquito net on the night before the interview. In contrast, only 3 percent of all women and 4 percent of pregnant women slept under an ITN. There is little difference in the use of nets between pregnant and non-pregnant women.

Data on use of nets by women show trends in regional variation similar to those found in the data on net ownership and use of nets by children under age five. Women in rural areas are more likely to have slept under a net the night before the interview than are urban women. Women in Preah Vihear/Steung Treng, Mondol Kiri/Rattanak Kiri, and Otdar Mean Chey are once again most likely to have slept under an ever-treated net or an ITN on the night before the interview. In Preah Vihear/Steung Treng and Otdar Mean Chey, pregnant women are much more likely than all women age 15-49 to have slept under an ever-treated net or an ITN.

The data in Table 16.3 are consistent with the trend of greater ever-treated net and ITN ownership and use among households in the lower wealth quintiles. Eighteen percent of pregnant women in the lowest wealth quintile slept under an ever-treated net the night before the interview, and 10 percent of women in this same group slept under an ITN. This compares to less than 1 percent of women in the highest wealth quintile sleeping under ever-treated nets or ITNs during the night before the interview.

Table 16.3 Use of mosquito nets by women

Percentage of all women age 15-49 and pregnant women age 15-49 who slept under a mosquito net (treated or untreated), an ever-treated mosquito net, or an insecticide-treated net (ITN) the night before the interview, by background characteristics, Cambodia 2005

¹ An ever-treated net is a pretreated net or a non-pretreated net which has subsequently been soaked with insecticide at any time.

² An insecticide-treated net (ITN) is 1) a factory-treated net that does not require any further treatment, or 2) a pretreated net obtained within the past 12 months, or 3) a net that has been soaked with insecticide within the past 12 months.

16.3 MALARIA DIAGNOSIS AND TREATMENT

Treatment of Malaria in Children

Malaria is not as prominent as acute respiratory infection (ARI) or diarrhea among children under age five in Cambodia. However, it is still the third leading cause of outpatient visits and the fourth leading cause of inpatient visits among children under age five (Department of Planning and Health Information, 2005). Treatment soon after the onset of fever, preferably within 24 hours, improves health outcomes among infected individuals.

Table 16.4 presents data on the percentage of children under age five with fever who received antimalarial drugs. Roughly one-third of children under the age of five years (35 percent) experienced fever in the two weeks preceding the survey, but treatment with antimalarial drugs was extremely low. Less than 1 percent of children with fever took any antimalarials. Although it is very difficult to analyze variation by background characteristics with such low usage of antimalarials, one may note that children with fever in Kratie and Krong Preah Sihanouk/Kaoh Kong are slightly more likely than children in other provinces to receive antimalarial drugs (3 percent).

Table 16.4 Prevalence and prompt treatment of children with fever

This chapter presents current levels of HIV/AIDS knowledge, attitudes, and related behaviors for the general adult population. The chapter then focuses on HIV/AIDS knowledge and patterns of sexual activity among young people. The findings in this chapter will assist the AIDS control program in Cambodia to identify particular groups of people most in need of information and services and most vulnerable to the risk of HIV infection.

17.1 KNOWLEDGE OF HIV/AIDS AND OF TRANSMISSION AND PREVENTION METHODS

17.1.1 Awareness of AIDS

Ninety-nine percent of women and men age 15-49 have heard of AIDS (Table 17.1). The level of awareness of AIDS among women is lowest in Mondol Kiri/Rattanak Kiri: only 73 percent of women know about AIDS. Among men, those living in Pursat are the least likely to know about AIDS (88 percent). Knowledge of AIDS exceeds 95 percent among women and men in all age groups, marital statuses, education levels, wealth quintiles, and by urban and rural residence.

17.1.2 HIV Prevention Methods

HIV/AIDS prevention programs focus their messages and efforts on three important aspects of behavior: delaying sexual debut in young persons (abstinence), limiting the number of sexual partners or staying faithful to one partner, and use of condoms (the ABC message). To ascertain whether programs have effectively communicated these messages, CDHS respondents were prompted with specific questions about whether it is possible to reduce the chances of getting the AIDS virus by having just one faithful sexual partner, using a condom at every sexual encounter, and abstaining from sex.

Table 17.2 presents levels of knowledge for the various HIV/AIDS prevention methods by background characteristics. Women are most knowledgeable about condoms for preventing transmission of the AIDS virus (87 percent) and are equally aware that the chances of getting the AIDS virus can be reduced by limiting sex to one uninfected partner who has no other partners (86 percent); knowledge of abstinence as a way to avoid AIDS was cited somewhat less frequently among women (83 percent). About 91 percent of men cite each of the three components of the ABCs of avoiding AIDS.

Table 17.2 Knowledge of HIV prevention methods

Percentage of women and men age 15-49 who, in response to prompted questions, say that people can reduce the risk of getting the AIDS virus by using condoms every time they have sexual intercourse, by having one sex partner who is not infected and has no other partners, and by abstaining from sexual intercourse, by background characteristics, Cambodia 2005

Background characteristic	Women					Men				
	Percentage who say HIV can be prevented by:					Percentage who say HIV can be prevented by:				
	Using condoms ¹	Limiting sexual intercourse to one uninfected partner ²	Using condoms, and limiting sexual intercourse to one uninfected partner ^{1,2}	Abstaining from sexual intercourse	Number of women	Using condoms ¹	Limiting sexual intercourse to one uninfected partner ²	Using condoms, and limiting sexual intercourse to one uninfected partner ^{1,2}	Abstaining from sexual intercourse	Number of men

na = Not applicable

¹ Every time they have sexual intercourse

² Who has no other partners

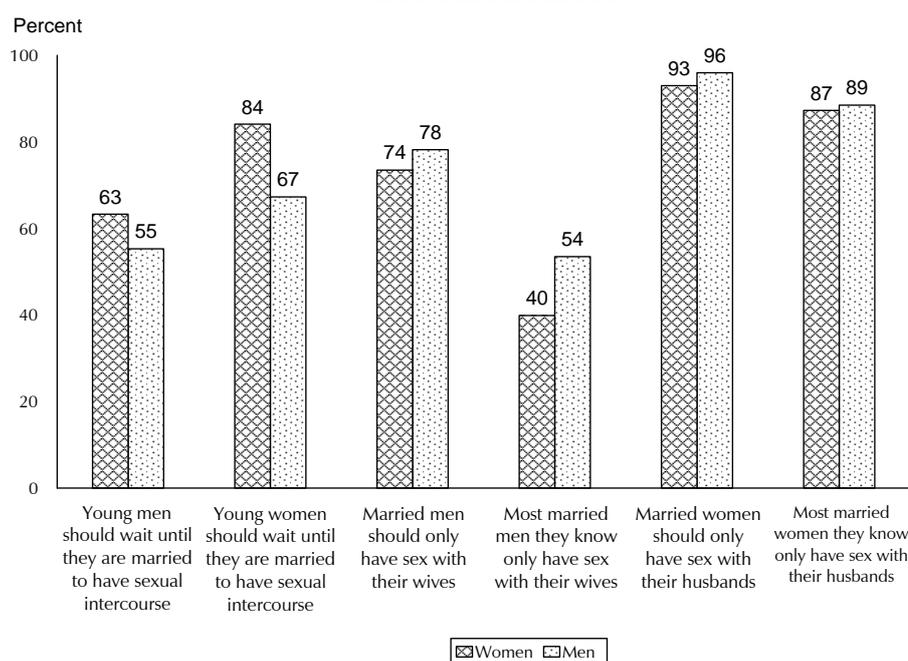

As Table 17.2 shows, women age 25-29 are somewhat more likely to have knowledge of the various modes of prevention than older women. Men age 20-24 are somewhat more likely to have knowledge about prevention of HIV/AIDS compared with older and younger men. There is little variation in knowledge of the various modes of prevention by marital status among either women or men; however, knowledge is higher among men who have never been married but have had sex.

Among both women and men, levels of knowledge of preventive methods are generally somewhat higher in urban than in rural areas. There is considerable variability across provinces in knowledge of prevention methods. Among women, knowledge of all three methods of prevention is highest in Phnom Penh and Otdar Mean Chey and lowest in Mondol Kiri/Rattanak Kiri. Among men, comprehensive knowledge is highest in Otdar Mean Chey and lowest in Pursat.

There is far more variability in knowledge across education levels and wealth quintiles than is seen across age, marital status, or residence. Women and men with higher levels of schooling are more likely than those with less schooling to be aware of various preventive methods. Similarly, women and men in higher wealth quintiles are more likely than those in lower quintiles to be aware of ways to prevent the transmission of the HIV virus.

Figure 17.1 reflects the perceptions and beliefs that Cambodian respondents have about abstinence and faithfulness. The majority of respondents believe that young women and men should wait until marriage to have sex, and that husbands and wives should only have sex with their spouses. Women tend to be more conservative than men in their views on sexual mores; however, men are somewhat more likely to hold themselves to a higher standard than women do on the question of whether men should have sex with only their wife: 74 percent of women agree with this statement, whereas 78 percent of men do. Married women's sexual behavior is held to a higher standard by both men and women: 93 percent of women and 96 percent of men believe a woman should only have sex with her husband. When it comes to perceptions of others' behavior, only 40 percent of women and 54 percent of men say that most married men they know stay faithful to their wives, while 87 percent of women and 89 percent of men say that most married women they know stay faithful to their husbands.

Figure 17.1 Perceptions and Beliefs about Abstinence and Faithfulness

CDHS 2005

17.1.3 Knowledge about Transmission

The 2005 CDHS included questions to assess the prevalence of common misconceptions about AIDS and HIV transmission. Respondents were asked whether they think it is possible for a healthy-looking person to have the AIDS virus. They were asked whether a person can get AIDS from mosquito bites, by supernatural means, or by sharing food with a person who has AIDS.

The results in Tables 17.3.1 and 17.3.2 indicate that many Cambodian adults lack accurate knowledge about the ways in which the AIDS virus can and cannot be transmitted. Particularly critical is the fact that only 69 percent of women and 60 percent of men know that a healthy-looking person can have (and thus transmit) the virus that causes AIDS. Many women and men also erroneously believe that AIDS can be transmitted by mosquito bites; however, 63 percent of women and 70 percent of men do reject this common misconception. Larger proportions of women and men are aware that the AIDS virus cannot be transmitted by supernatural means (83 percent and 90 percent, respectively) or by sharing food with a person who has AIDS (87 percent for both women and men). Overall, less than half of women (48 percent) and men (44 percent) are able to reject two of the more common misconceptions about AIDS—that AIDS can be transmitted by mosquito bites and that a person can become infected with the AIDS virus by sharing food with someone who is infected—and know that a healthy-looking person can have the AIDS virus.

Tables 17.3.1 and 17.3.2 also provide an assessment of the level of comprehensive knowledge of HIV/AIDS prevention and transmission. Comprehensive knowledge is defined as: 1) knowing that both condom use and limiting sex partners to one uninfected person are HIV/AIDS prevention methods, 2) being aware that a healthy-looking person can have HIV, and 3) rejecting the two most common local misconceptions—that HIV/AIDS can be transmitted through mosquito bites and by sharing food. According to the CDHS results, 44 percent of women and 41 percent of men in Cambodia have comprehensive knowledge of HIV/AIDS prevention and transmission.

Finally, Tables 17.3.1 and 17.3.2 document considerable variation in HIV/AIDS knowledge. Sexually active, never-married men tend to be more knowledgeable than men in other marital status categories. For all indicators, the proportion of women and men with correct knowledge about HIV/AIDS prevention and transmission is higher in urban than rural areas. Variations in knowledge levels by province are marked among both women and men, with the highest levels of comprehensive knowledge about AIDS observed among female residents of Battambang/Krong Pailin (74 percent) and among male residents of Kandal (68 percent).

Education and wealth are strongly associated with both correct knowledge concerning common misconceptions and comprehensive knowledge of HIV/AIDS prevention and transmission. Among women, for example, 72 percent of women with a secondary or higher education have comprehensive knowledge about prevention and transmission modes compared with 22 percent of women with no education. Among men, the level of comprehensive knowledge varies from 17 percent among those with no education to 58 percent of those with a secondary or higher education.

Table 17.3.1 Comprehensive knowledge about AIDS: women

Percentage of women age 15-49 who say that a healthy-looking person can have the AIDS virus and who, in response to prompted questions, correctly reject local misconceptions about AIDS transmission or prevention, and the percentage with a comprehensive knowledge about AIDS by background characteristics, Cambodia 2005

Background characteristic	Percentage of women who say that:				Percentage who say that a healthy-looking person can have the AIDS virus and who reject the two most common local misconceptions ¹	Percentage with a comprehensive knowledge about AIDS ²	Number of women
	A healthy-looking person can have the AIDS virus	AIDS cannot be transmitted by mosquito bites	AIDS cannot be transmitted by supernatural means	A person cannot become infected by sharing food with a person who has AIDS

17.1.4 Knowledge of Mother-to-Child Transmission

Educating people in the ways in which HIV can be transmitted from mother to child and the fact that the risk of transmission can be reduced by taking antiretroviral drugs is critical to reducing mother-to-child transmission (MTCT) of HIV. To obtain information on these issues, respondents were asked if the virus that causes AIDS can be transmitted from a mother to a child during breastfeeding and whether a mother with HIV can reduce the risk of transmission to the baby by taking certain drugs (antiretrovirals) during pregnancy (see Table 17.4).

Although 87 percent of women and 84 percent of men know that HIV can be transmitted by breastfeeding, only one-third of women and about one-fourth of men know that the risk of MTCT can be reduced through the use of certain drugs during pregnancy. Thirty-one percent of women and 21 percent of men have comprehensive knowledge of MTCT—they are aware of both aspects of MTCT transmission.

There are no marked differences in MTCT knowledge among women and men by age, marital status, or pregnancy status (for women); however, there is considerable variation by residence, education, and wealth. While most respondents know that HIV can be transmitted by breastfeeding, it is the lack of knowledge about antiretrovirals that account for most of the variation by background characteristics. Comprehensive knowledge about mother-to-child transmission is highest among men and women living in urban areas. Women living in Battambang/Krong Pailin are most knowledgeable about MTCT (57 percent have comprehensive knowledge), while the same can be said of men living in Kampong Speu and Prey Veng, each having one-third of men with comprehensive knowledge. Knowledge levels are lowest among women and men who have no education, and among those who are in the lowest wealth quintile. Particularly notable is the comparatively low level of knowledge among pregnant women; just 30 percent of pregnant women are aware both that HIV can be transmitted from mother to child during breastfeeding and that mother-to-child transmission can be reduced by taking certain drugs during pregnancy. This indicates that there is currently incomplete coverage of MTCT counseling during prenatal care visits in Cambodia.

Table 17.4 Knowledge of prevention of mother-to-child transmission of HIV

Percentage of women and men age 15-49 who know that HIV can be transmitted from mother to child by breastfeeding and that the risk of mother-to-child transmission (MTCT) of HIV can be reduced by mother taking special drugs during pregnancy, by background characteristics, Cambodia 2005

Background characteristic	Women				Men

17.2 STIGMA ASSOCIATED WITH AIDS AND ATTITUDES RELATED TO HIV/AIDS

Knowledge and beliefs about AIDS affect how people treat those they know to be living with HIV. In the 2005 CDHS, a number of questions were posed to respondents to measure their attitudes towards HIV-infected people, including questions about their willingness to buy vegetables from an infected vegetable seller, to let others know the HIV status of family members, and to take care of relatives who have the AIDS virus in their own household. They were also asked whether an HIV-positive female who is not sick should be allowed to continue teaching. Tables 17.5.1 and 17.5.2 show the percentages who express positive attitudes towards people with HIV among women and men who have heard about HIV/AIDS by background characteristics.

Both women and men tend to express more positive attitudes in response to the questions concerning behavior towards HIV-infected relatives and teachers than to the questions about shopkeepers. Seventy-seven percent of women and 83 percent of men say they would be willing to care for a family member with the AIDS virus in their home; 79 percent of women and 81 percent of men say that an HIV-positive teacher should be allowed to continue teaching. Comparatively fewer (64 percent of women and 73 percent of men) would buy fresh food from a shopkeeper with AIDS. The percentage expressing accepting attitudes on all four measures is 36 percent among women and 32 percent among men.

Among men, wealth is related to some measures of accepting attitudes towards those who are HIV positive. For example, willingness to care for a family member who has HIV varies little by wealth quintile. However, willingness to buy fresh vegetables from someone with HIV, or believing that an HIV-positive female teacher who is not sick should be allowed to continue teaching are positively and monotonically related to wealth: as wealth increases, so do the proportions of respondents who hold these accepting attitudes towards those who are HIV positive. For both men and women, increasing levels of education are associated with increasing levels of accepting attitudes towards people living with HIV.

Table 17.5.1 Accepting attitudes toward those living with HIV/AIDS: women

Among women age 15-49 who have heard of AIDS, percentage expressing specific accepting attitudes toward people with AIDS, by background characteristics, Cambodia 2005

Background characteristic	Percentage of women who:				Percentage expressing attitudes on all four indicators	Number of women who have heard of AIDS
	Are willing to care for a family member with the AIDS virus in the respondent's home	Would buy fresh vegetables from shopkeeper who has the AIDS virus	Say that a female teacher with the AIDS virus and is not sick should be allowed to continue teaching	Would not want to keep secret that a family member got infected with the AIDS virus

17.3 ATTITUDES TOWARDS NEGOTIATING SAFER SEX AND EDUCATING YOUTH ABOUT CONDOM USE

Knowledge about HIV transmission and ways to prevent it are of little use if people feel powerless to negotiate safer sex practices with their partner. In an effort to assess the ability of women to negotiate safer sex with a spouse who has an STI, CDHS respondents were asked if they thought a wife is justified in refusing to have sex with her husband when she knows he has a disease that can be transmitted through sexual contact, and if a woman in the same circumstances is justified in asking her husband to use a condom. Similarly, youth need to have sufficient knowledge about HIV/AIDS and condoms to be able to negotiate and protect themselves once they become sexually active. To gauge the extent of support for programs to increase condom knowledge among youth, all CDHS respondents (youth and adults) were asked whether they thought that children age 12-14 should be taught about using condoms to avoid AIDS.

Table 17.6 shows that 95 percent of women and 99 percent of men believe that, if she knows her husband has an STI, a woman is justified in either refusing to have sex with him or asking him to wear a condom. Considering the two actions separately, the majority of both women (85 percent) and men (96 percent) say that a woman can refuse to have sex.

The majority of respondents in all groups support a woman's right to negotiate safer sex. However, there are small differences by background characteristics in the percentages of respondents holding this opinion. For example, the higher a respondent's educational attainment, the more likely he or she is to say that a woman can refuse sex or propose using a condom. Support for women's negotiating rights also tends to increase across wealth quintiles among both women and men. The proportions supporting a woman's right to negotiate safer sex varies across provinces. Among women, the percentage saying that a woman is justified in refusing sex or asking that a condom be used ranges from a low of 69 percent in Mondol Kiri/Rattanak Kiri to 100 percent in Kampong Chhnang, Svay Rieng, Otdar Mean Chey, and Battambang/Krong Pailin. Among men, support for women's negotiating rights is also lowest in Mondol Kiri/Rattanak Kiri (94 percent), though it is much higher than among women in those same provinces. Men's support for women's rights to negotiate sex is 99 percent or higher in 12 of the 19 provinces.

Table 17.6 Attitudes toward negotiating safer sexual relations with husband

Percentage of women¹ and men age 15-49 who believe that if a husband has a sexually transmitted disease his wife is justified in refusing to have sexual relations with him or in asking that they use a condom, by background characteristics, Cambodia 2005

Background characteristic	Women				Men			
	Woman is justified in:			Number of women	Woman is justified in:			Number of men

Note: An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.

¹ Among women who were administered the women's status module.

Table 17.7 shows the percentage of women and men who agree that children age 12-14 years should be taught about using a condom to avoid AIDS. About half (54 percent) of women agree that children should be taught about condom use, whereas 69 percent of men agree. There is little consistent variation by age, marital status, education, or wealth. The greatest variation occurs by province: respondents from Mondol Kiri/Rattanak Kiri are the least likely to agree that children should be taught to use condoms (26 percent of women and 58 percent of men), while respondents from Otdar Mean Chey are most likely to agree (82 percent of women and 100 percent of men).

17.4 HIGHER-RISK SEX

Given that most HIV infections in Cambodia are contracted through heterosexual contact, information on sexual behavior is important in designing and monitoring intervention programs to control the spread of the epidemic. In the context of HIV/AIDS prevention, limiting the number of sexual partners and having protected sex are crucial to combating the epidemic.

The 2005 CDHS included questions on respondents' sexual partners during the 12 months preceding the survey. For male respondents, an additional question was asked on whether they paid for sex during the 12 months preceding the interview. Information on the use of condoms at the last sexual encounter with each type of partner was collected from both women and men. Finally, sexually active women and men were asked about the total number of partners they had during their lifetime. These questions are of course sensitive, and in interpreting the results in this section it is important to remember that respondents' answers are likely subject to at least some reporting bias.

17.4.1 Multiple Sexual Partners and Higher-Risk Sex

Tables 17.8.1 and 17.8.2 present several indicators based on information collected from sexually-active women and men about their sexual partners during the 12-month period before the survey and over their lifetime. The first two indicators in the tables assess the prevalence of multiple partners and of higher-risk sexual intercourse among women and men who reported having intercourse during the 12 months prior to the survey. Higher-risk sex involves sexual intercourse with a partner who is neither a spouse nor a cohabiting partner. The third indicator (for men only) relates to condom use during the last higher-risk sexual encounter. The fourth indicator, the mean number of sexual partners that a woman or man has had during their lifetime, provides an assessment of lifetime exposure to one of the elements of higher-risk sex, multiple partners.

The tables show that, among those who had sex in the previous 12 months, less than 1 percent of women age 15-49 report having had two or more sexual partners during the period, while 10 percent of men age 15-49 have had two or more partners. Almost no women report having had higher-risk sexual intercourse in the past 12 months (i.e., sexual intercourse with someone other than their spouse or cohabiting partner); the overall prevalence is one tenth of one percent. However, 14 percent of men report higher-risk sex in the past year.

The differentials presented in the tables suggest that higher-risk sex, particularly among men, is concentrated in a limited number of population subgroups. First, the prevalence of higher-risk sex is by definition universal among never-married men who reported having sexual intercourse during the 12-month period prior to the CDHS.¹ Looking at the other marital status categories, very few women who were currently in union (less than 1 percent) reported higher-risk sexual encounters during the 12 months prior to the survey. Divorced women were most likely to have had higher-risk sex in the past year: 3 percent report having had sex with a noncohabiting partner. Seven percent of married men and 71 percent of divorced, separated or widowed men said they had engaged in higher-risk sex in the previous 12 months.

Because many respondents in the 15-24 age group are likely to be never-married, it is expected that higher-risk sex would be more prevalent in these cohorts than among older women and men. What is somewhat surprising is the size of the gender differential in the reporting of these sexual behaviors among respondents in this age range. For example, 36 percent of men age 15-24 who had sexual intercourse during the 12-month period prior to the survey reported that they had engaged in higher-risk sex compared with less than 1 percent of women in the same cohort. The size of the differential suggests that sexually active men age 15-24 are having paid sex.

¹ To determine marital status, the CDHS asked respondents whether or not they were currently or had ever been married or lived together with a partner. Thus, by definition, sexual intercourse among respondents classified as never-married is high risk, i.e., it involves a nonmarital, noncohabiting partner.

Table 17.8.1 Multiple sexual partners and higher-risk sexual intercourse in the past 12 months: women

Among women age 15-49 who had sexual intercourse in the past 12 months, the percentage who had intercourse with more than one partner and the percentage who had higher-risk sexual intercourse in the past 12 months, and the mean number of sexual partners during her lifetime for women who ever had sexual intercourse, by background characteristics, Cambodia 2005

¹ Sexual intercourse with a nonmarital, noncohabiting partner

Considering the other variables in Tables 17.8.1 and 17.8.2, higher-risk sex among both women and men is most prevalent among those living in urban areas and in Phnom Penh. Higher-risk sex increases directly with education and wealth: as education and wealth increase, so does risky sexual behavior. However, these relationships are apparent only for men, since so few women engage in higher-risk sexual activity.

As mentioned above, condom use is an important tool in the fight to curtail the spread of HIV/AIDS. Although truly effective protection would require condom use at every sexual encounter, the most important sexual encounters to cover are those considered to be “higher risk,” i.e., sex with a nonmarital, noncohabiting partner in the 12 months preceding the survey. Table 17.8.2 shows that, among men reporting that they engaged in higher-risk sex during the 12-month period prior to the survey, 83 percent reported that a condom was used the last time they had higher-risk intercourse. The numbers of respondents reporting higher-risk sex are frequently quite small, making it difficult to assess differences in the prevalence of condom use across subgroups. However, the results suggest that, among men who engaged in higher-risk sex, condom use is highest among urban residents, those with a secondary or higher education, and those in the highest wealth quintile.

Finally, Tables 17.8.1 and 17.8.2 show that men who have ever been sexually active report having an average (mean number) of 5 lifetime sexual partners, five times the average reported by women who have ever been sexually active (1 partner). Divorced, separated or widowed men report the highest mean lifetime number of partners (12 partners); it is not known whether the comparatively large number of partners among these men is a cause or a consequence of their divorced/separated status. Provinces in which the mean number of lifetime partners among men is comparatively higher include Krong Preah Sihanouk/Kaoh Kong (11 partners) and Phnom Penh (9 partners).

17.4.2 Paid Sex

Paid sex is considered a special category of higher-risk sex. Male respondents in the 2005 CDHS were asked whether they had paid money in exchange for sex in the past 12 months or if any of their last three partners in the past 12 months was a commercial sex worker.

Six percent of men had engaged in paid sex in the 12 months before the survey (Table 17.9). The highest percentages of men reporting that they had engaged in paid sex are observed among men in Phnom Penh (15 percent) and in Krong Preah Sihanouk/Kaoh Kong (10 percent). Men between the ages of 20 and 29 are most likely to report having paid money for sex compared with other age groups. Urban men and the wealthiest men are much more likely to report having paid for sex in the past year. Divorced men are particularly at risk for having paid sex, with 22 percent having engaged in such a transaction in the past year. Where numbers are sufficiently high for analysis, the table indicates that nearly all men who paid for sex in the last year used a condom at last paid sex.

Table 17.9 Payment for sexual intercourse and condom use at last paid sexual intercourse: men

Percentage of men age 15-49 reporting payment for sexual intercourse in the past 12 months, and among them, the percentage reporting that a condom was used the last time they paid for sexual intercourse, by background characteristics, Cambodia 2005

17.5 TESTING FOR HIV

Knowledge of HIV status helps HIV-negative individuals make specific decisions to reduce risk and increase safer sex practices so they can remain disease free. For those who are HIV infected, knowledge of their status allows them to take action to protect their sexual partners, to access treatment, and to plan for the future. Testing of pregnant women is especially important so action can be taken to prevent mother-to-child transmission.

To obtain information on the prevalence of HIV testing, all respondents were asked whether they had ever been tested for HIV. If they said that they had, respondents were asked whether they had received the results of their last test. Women giving birth in the two-year period before the survey were asked additional questions regarding testing that may have occurred as part of any antenatal care they received prior to the birth.

Tables 17.10.1 and 17.10.2 show that, among the adult population age 15-49, 10 percent of women and 15 percent of men have been tested for HIV at some time. The majority of women and men who were tested indicated that they had received the results of their test. Three percent of women and 5 percent of men said that they had received results from an HIV test taken during the 12 months prior to the survey. Among both women and men, the proportions ever tested are higher among those age 20 and older than those younger than 20. Considering marital status, testing rates are highest among ever-married women, while for men testing is most likely among never-married men who have ever had sex (26 percent) and among widowed, divorced and separated men (36 percent). Considering the other characteristics for which results are presented in the tables, the highest testing rates are observed among urban residents, residents of Phnom Penh, those with a secondary or higher education, and those in the highest wealth quintile.

Table 17.10.1 Coverage of prior HIV testing: women

Percentage of women age 15-49 who know where to get an HIV test, percent distribution of women age 15-49 by testing status and by whether they received the results of the last test, the percentage of women ever tested, and the percentage of women age 15-49 who received their test results the last time they were tested for HIV in the past 12 months, according to background characteristics, Cambodia 2005

Background characteristic	Percentage who know where to get an HIV test	Percent distribution of women by testing status and by whether they received the results of the last test				Total	Percentage ever tested	Percentage who received results from last HIV test taken in the past 12 months	Number of women
		Ever tested and received results	Ever tested, did not receive results	Never tested ¹

Table 17.11 presents data on HIV/AIDS information and counseling during antenatal care. Among women who gave birth in the past two years, 16 percent received information and counseling about HIV/AIDS during antenatal care for their most recent birth. Twelve percent of the women reported that they were offered and accepted an HIV test during antenatal care. Taking both these elements into account, the CDHS results indicate that only 8 percent of women giving birth during the two-year period prior to the survey were counseled about HIV, voluntarily accepted an offer of an HIV test, and received the test results. Women who gave birth during the two-year period before the survey were most likely to have received HIV/AIDS counseling and testing services during antenatal care if they lived in an urban area (26 percent), especially in Phnom Penh (35 percent). Other provinces where pregnant women were comparatively more likely to receive comprehensive HIV/AIDS counseling, testing and results include Siem Reap (22 percent) and Battambang/Krong Pailin (13 percent). Women with secondary or higher education were nearly four times more likely than those with no education, and three times as likely as those with primary education, to obtain full counseling and testing services during pregnancy. While access to full counseling and testing services does increase with wealth, it remains fairly low for all quintiles save for the wealthiest: pregnant women living in households that fall into the wealthiest quintile are more than three times as likely to have received counseling and testing for HIV than women in the fourth highest quintile, and are 20 times more likely to receive these services than women from the poorest quintile.

Table 17.11 Pregnant women counseled and tested for HIV

Among all women age 15-49 who gave birth in the two years preceding the survey, the percentage who received HIV counseling during antenatal care for their most recent birth, and percentage who accepted an offer of HIV testing by whether they received their test results, according to background characteristics, Cambodia 2005

Background characteristic	Percentage who received HIV counseling during antenatal care ¹	Percentage who were offered and accepted an HIV test during antenatal care and who ² :		Percentage who were counseled, were offered and who accepted an HIV test, and who received results ²	Number of women who gave birth in the past two years ³
		Received results	Did not receive results

¹ In this context, "counseled" means that someone talked with the respondent about all three of the following topics: 1) babies getting the AIDS virus from their mother, 2) preventing the virus, and 3) getting tested for the virus.

² Only women who were offered the test are included here. Women who were either required or asked for the test are excluded from the numerator of this measure.

³ Denominator for percentages includes women who did not receive antenatal care for their last birth in the past two years.

17.6 REPORTS OF RECENT SEXUALLY TRANSMITTED INFECTIONS

Information about the incidence of sexually transmitted infections (STIs) is not only useful as a marker of unprotected sexual intercourse but also as a cofactor for HIV transmission. The 2005 CDHS asked respondents who had ever had sex whether they had had an STI in the past 12 months. They were also asked whether, in the past year, they had experienced a genital sore or ulcer, and whether they had any genital discharge. These symptoms have been shown useful in identifying STIs in men. They are less easily interpreted in women because women are likely to experience more non-STI conditions of the reproductive tract that produce a discharge.

Table 17.12 shows that about 10 percent of women and 2 percent of men who have ever been sexually active had an STI and/or STI symptoms in the 12 months prior to the survey. Those reporting STI symptoms were somewhat more likely to say they had had an abnormal genital discharge than to report a genital ulcer.

Figure 17.2 shows that, among those reporting a sexually transmitted infection or symptom thereof in the past year, women are more likely to seek treatment than men. Moreover, among those who do seek treatment, women are more likely to seek treatment from a health professional than are men.

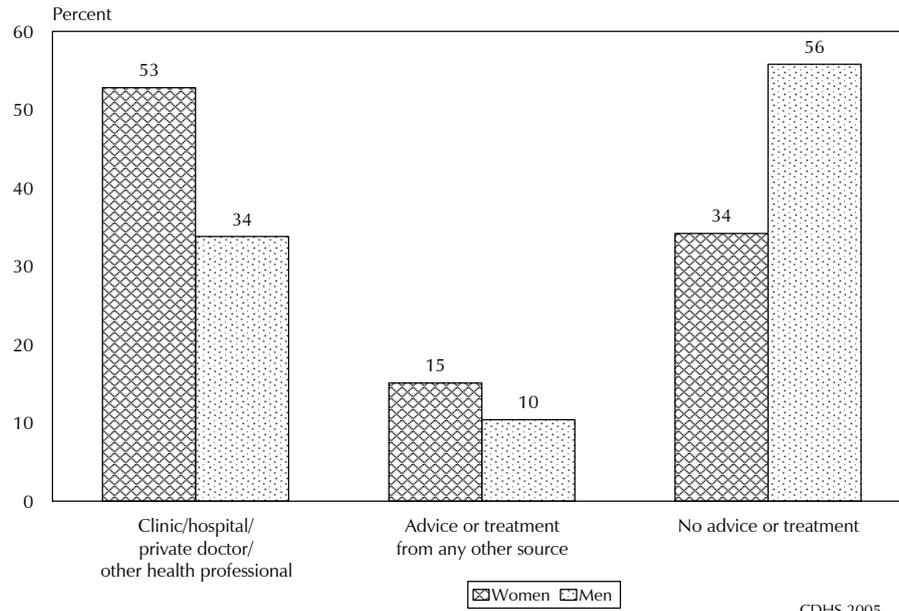

Table 17.12 Self-reported prevalence of sexually-transmitted infections (STIs) and STI symptoms

Among women and men age 15-49 who ever had sexual intercourse, the percentage reporting having an STI and/or symptoms of an STI in the past 12 months, by background characteristics, Cambodia 2005

Figure 17.2 Women and Men Seeking Treatment for STIs

17.7 INJECTIONS

Injection overuse in a health care setting can contribute to the transmission of blood-borne pathogens because it amplifies the effect of unsafe practices such as reuse of injection equipment. As a consequence, the proportion of injections given with reused injection equipment is an important prevention indicator in an initiative to control the spread of HIV/AIDS.

Table 17.13 presents data on the prevalence of injections among respondents. Respondents were asked if they had had any injections given by a health worker in the 12 months preceding the survey, and if so, the number of injections they had received and whether their last injection was given with a syringe from a new, unopened package. It should be noted that medical injections can be self-administered (e.g., insulin for diabetes). These injections were not included in the calculations.

Women are more likely than men to report receiving at least one injection (36 percent and 29 percent, respectively). The average number of injections received from a health provider was 2 injections among women and 1 injection among men.

Table 17.13 shows that the largest variations in the injection prevalence indicator are across regions. Among women, for example, the percentage reporting they had received at least one injection from a health worker during the 12 months prior to the survey varies from a low of 16 percent in Mondol Kiri/Rattanak Kiri to a high of 60 percent among women in Otdar Mean Chey. Among men, the likelihood of having received an injection is lowest in Kratie (9 percent) and highest in Kampong Cham (44 percent). Urban residents are somewhat less likely than rural residents to have received at least one injection from a health provider. The associations between receiving at least one injection from a health provider and background characteristics such as education and wealth are not consistent in direction.

The majority of recent injections (98 percent among women and 96 percent among men) were given with a needle and syringe taken from a newly opened package. Women living in Krong Preah Sihanouk/Kaoh Kong are the least likely to report that the injection was given using a needle and syringe from a previously unopened package (84 percent).

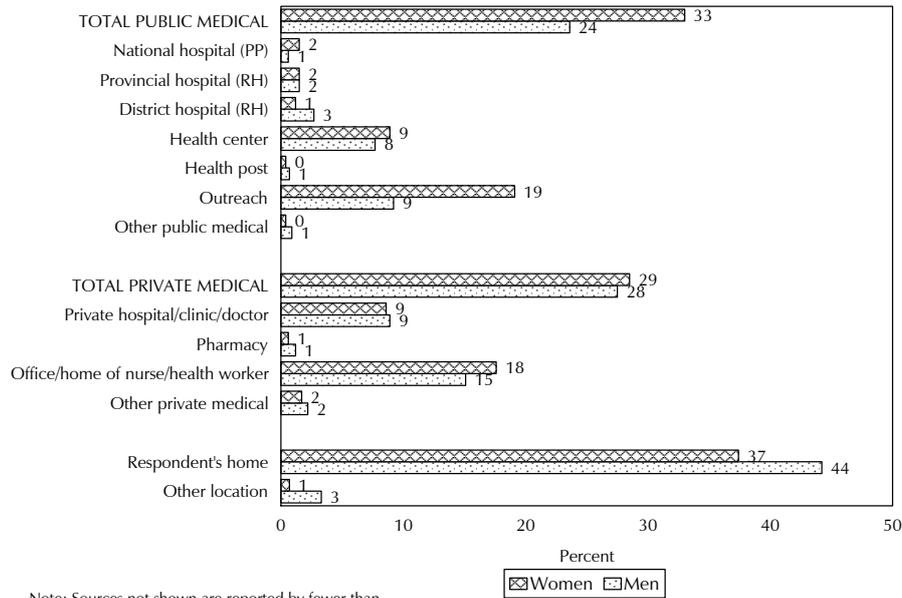

Table 17.13 Prevalence of medical injections

Percentage of women and men age 15-49 who received at least one medical injection in the last 12 months, the average number of medical injections per person in the last 12 months, and among those who received a medical injection, the percentage of last medical injections for which the syringe and needle were taken from a new, unopened package, by background characteristics, Cambodia 2005

Background characteristic	Women					Men

Note: Medical injections are those given by a doctor, nurse, pharmacist, dentist or other health worker. Figures in parentheses are based on 25-49 unweighted cases.

Figure 17.3 Type of Facility Where Last Medical Injection Was Received

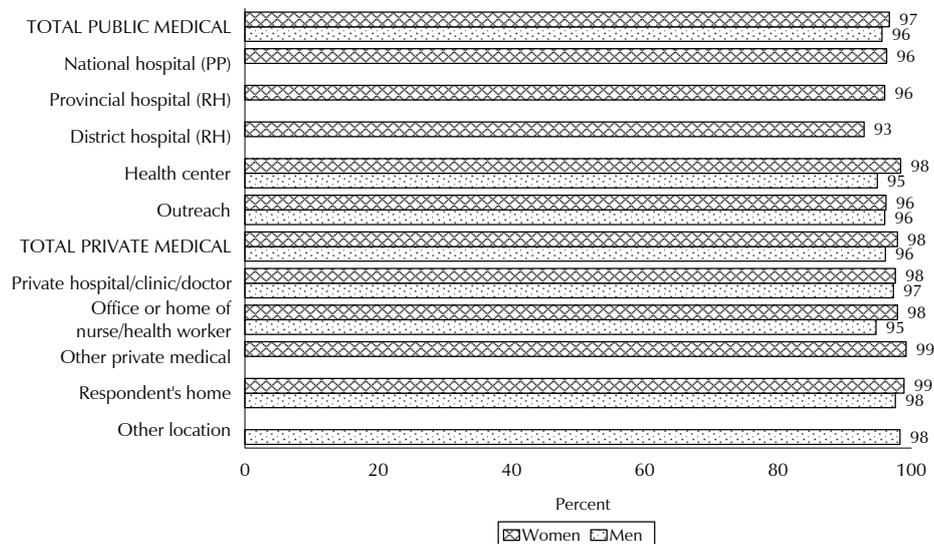

Note: Sources not shown are reported by fewer than 0.5 percent of women and men.

CDHS 2005

It is interesting to note that for both men and women, the largest proportion of most recently received medical injections were administered in a home, rather than a medical, setting. Among women, the next most common places to obtain a medical injection were at outreach facilities (19 percent) or at the office or home of a nurse or medical worker (18 percent). Among men, the next most common place to obtain a medical injection was also at the office or home of a nurse or medical worker (15 percent). Figure 17.4 demonstrates that the vast majority of injections are administered with a syringe and needle taken from a new, unopened package; only at District hospitals do proportions of injections administered with new equipment fall below 95 percent.

Figure 17.4 Percentage Whose Last Injection Was Given With a Syringe and Needle Taken From a New, Unopened Package

Note: Sources not shown are reported by fewer than 50 unweighted cases.

CDHS 2005

17.8 HIV/AIDS-RELATED KNOWLEDGE AND BEHAVIOR AMONG YOUTH

Knowledge of HIV/AIDS issues and related sexual behavior among youth age 15-24 is of particular interest because the period between sexual initiation and marriage is for many young people a time of sexual experimentation that may involve high-risk behaviors. This section considers a number of issues that relate to both transmission and prevention of HIV/AIDS among youth, including the extent to which youth have comprehensive knowledge of HIV/AIDS transmission and prevention modes and knowledge of a source where they can obtain condoms. Issues such as abstinence, age at sexual debut, and condom use are also covered in this section.

17.8.1 Knowledge about HIV/AIDS and Source for Condoms

Knowledge of how HIV is transmitted is crucial to enabling young people to avoid AIDS. Young people are often at greater risk because they may have shorter relationships with more partners or engage in other risky behaviors. As discussed earlier, comprehensive knowledge is defined as knowing that: 1) people can reduce their chances of getting the AIDS virus by having sex with only one uninfected, faithful partner and by using condoms consistently; 2) a healthy-looking person can have the AIDS virus; and 3) HIV cannot be transmitted by mosquito bites or by sharing food with a person who has AIDS.

Table 17.14 shows that only half of women and nearly half of men age 15-24 know all of these facts about HIV/AIDS. The level of comprehensive knowledge about HIV/AIDS does not vary consistently by age within the youth population. Among young women, comprehensive knowledge is somewhat higher among the never-married than the ever-married (52 percent compared with 47 percent). Among young men, comprehensive knowledge is highest among those who have never married but have ever had sex (60 percent).

As expected, comprehensive HIV/AIDS knowledge is much more common among urban than rural youth. Among young women, the level of comprehensive knowledge ranges from a low of 11 percent in Mondol Kiri/Rattanak Kiri to a high of 80 percent in Battambang/Krong Pailin. Among young men, comprehensive knowledge is lowest in Svay Rieng (3 percent) and highest in Kandal (75 percent). Young women with a secondary education or higher are four times as likely as those with no schooling to have comprehensive knowledge of HIV/AIDS, while highly educated young men are three times as likely as those with no education to have comprehensive knowledge. Comprehensive knowledge about HIV/AIDS among youth increases with household wealth.

Because of the important role that condoms play in combating the transmission of HIV, respondents were asked whether they knew where condoms could be obtained. Only responses about “formal” sources were counted; friends and family and other similar sources were not included.

As shown in Table 17.14, young women are more likely than young men to know where to obtain a condom (53 and 47 percent, respectively). Among either sex, knowledge of a condom source tends to increase with age. Ever-married young women are more likely to know about a source for condoms than those who have never married, while among young men, it is the never-married men who have ever had sex who are the most likely to have this knowledge. Among both young women and men, those in urban areas are more likely than those in rural areas to know of a condom source. Knowledge of a condom source among women is lowest in Mondol Kiri/Rattanak Kiri (19 percent) and highest in Battambang/Krong Pailin (93 percent); among men, this knowledge is least in Banteay Mean Chey (18 percent) and greatest in Battambang/Krong Pailin (83 percent). Consistent with the patterns observed for other indicators, youth who are better educated and live in wealthier households are more likely than other youth to know a source of condoms.

Table 17.14 Comprehensive knowledge about AIDS and of a source of condoms among youth

Percentage of young women and young men age 15-24 with comprehensive knowledge about AIDS and percentage with knowledge of a source of condoms, by background characteristics, Cambodia 2005

¹ Comprehensive knowledge means knowing that consistent use of condom during sexual intercourse and having just one uninfected faithful partner can reduce the chance of getting the AIDS virus, knowing that a healthy-looking person can have the AIDS virus, and rejecting the two most common local misconceptions about AIDS transmission or prevention. The components of comprehensive knowledge are presented in Tables 17.2, 17.3.1, and 17.3.2.

² Friends, family members, and home are not considered sources for condoms.

17.8.2 Age at First Sex and Condom Use at First Sexual Intercourse

Information from the CDHS can be used to look at several important issues relating to the initiation of sexual activity among youth including age at first sex and condom use at first sexual intercourse.

Table 17.15 shows the proportions of women and men in the 15-24 age cohort who had sex before age 15 and before age 18. One percent of young women and less than one percent of young men had sex by age 15, while 17 percent of young women and 7 percent of young men had sex by age 18.

¹ Friends, family members, and home are not considered sources for condoms.
na = Not available

In Cambodia, it is rare for women to have sex prior to marriage; therefore, since the median age at first marriage among Cambodian women is 20.1 years, very few women report that they have had sex before the age of 15. The exception is found among women who live in Mondol Kiri/Rattanak Kiri, who, perhaps by virtue of having a comparatively younger median age at first marriage of 18.6 years, are most likely to report having had sexual intercourse before the age of 15 (9 percent).

Among women age 18-24, young women age 18-19 were less likely than those age 20-24 to say they had initiated sex before age 18. Young women in urban areas are slightly more likely to have had sex by age 15 than young women in rural areas; however, rural girls age 18-24 are more likely than urban girls of the same age to have had sex by age 18. While only 11 percent of women age 18-24 in Kampong Thom report having had sex before the age of 18, the corresponding figure for women in Mondol Kiri/Rattanak Kiri is 41 percent. Education and wealth have a negative association with early initiation of sexual activity: as education and wealth increase, the proportion of women reporting sex before the age of 18 decreases.

Differentials in these indicators for young men tend to be minor. This is at least in part because the proportions initiating sexual activity at an early age are not large in most subgroups with the exception of those living in the provinces of Mondol Kiri/Rattanak Kiri, and to a lesser extent those living in Kampong Krong and Battambang/Krong Pailin (20 percent, 13 percent, and 12 percent, respectively, report having had sex before the age of 18).

To assess the extent of condom use from the beginning of sexual exposure, respondents age 15-24 were asked whether they had used condoms the first time they had sex. Table 17.16 shows that 3 percent of young women and 42 percent of young men used condoms during their first sexual encounter. It is not surprising that so few women report condom use at first sex, since most Cambodian women are newly married at the time of their first sex, and are therefore unlikely to use contraception. Never-married men were much more likely than ever-married youth to have used a condom during their first sexual intercourse (84 percent compared with 21 percent). Higher educational attainment, greater wealth, and urban residence are related to a greater likelihood that condoms were used the first time a young man had sex.

17.8.3 Recent Sexual Activity

The period between age at first sex and age at marriage is often a time of sexual experimentation. Unfortunately, in the era of HIV/AIDS, it can also be a risky time. Table 17.17 presents data on the percentage of never-married young women and men age 15-24 who have not yet engaged in sex, the percentage who had sex in the 12 months preceding the survey, and the percentage who used condoms during their most recent sexual intercourse.

The great majority of never-married young women (99.8 percent) and men (89 percent) reported that they had never had sex, and, as a result, the proportions reporting recent sexual activity (i.e., within the 12-month period before the survey) are low (0.1 percent among young women and 8 percent among young men).

Given the comparatively small proportion of never-married young women reporting premarital sexual intercourse, differentials in this indicator are generally minimal. Among never-married young men, the proportion reporting premarital sexual activity tends to increase with age, education, and wealth, and is higher among urban than rural residents. Looking at provincial variations, Phnom Penh has the highest proportion of never-married young men reporting premarital sex (26 percent).

Table 17.17 Premarital sexual intercourse and condom use during premarital sexual intercourse among youth

Among never-married women and men age 15-24, the percentage who have never had sexual intercourse, the percentage who had sexual intercourse in the past 12 months, and, among never-married men age 15-24 who had premarital sexual intercourse in the past 12 months, the percentage who used a condom at the last sexual intercourse, by background characteristics, Cambodia 2005

¹ Friends, family members, and home are not considered sources for condoms.

17.8.4 Higher-Risk Sex

The most common mode of transmission of HIV in Cambodia is through unprotected sex with an infected person. To prevent HIV/AIDS transmission, it is important that young people practice safe sex through the much-advocated ABC method (abstinence, being faithful to one uninfected partner, and condom use). Tables 17.18.1 and 17.18.2 present data on the percentage of young people engaging in higher-risk sex (sex with a nonmarital, noncohabiting partner) in the 12-month period preceding the survey, and the rate of condom use in these higher-risk sexual encounters (Table 17.18.2 only). Among sexually active youth age 15-24, less than 1 percent of women and 36 percent of men engaged in higher-risk sexual activity in the past 12 months. Due to the small numbers of women who have engaged in higher-risk sex, no data can be shown regarding condom use at last high risk sexual intercourse. Eighty-four percent of these men reported condom use in their last higher-risk encounter.

Among young men, there are considerable differences in the prevalence of higher-risk sex by background characteristics. Wealthier youth and youth with a secondary or higher education are much more likely than those with less wealth or schooling to have engaged in higher-risk sex. Urban youth are considerably more likely than rural youth to have engaged in risky sexual behavior.

Figure 17.5 shows that most young women age 15-24 have not yet had sexual intercourse; among those who have had sex, it has been with one partner only and no condom has been used. Virtually all women who have had sex are married (see Table 17.17.1). Figure 17.5 also demonstrates that the vast majority of men age 15-19 have not yet had sexual intercourse, but by age 20-24, over half have engaged in sexual intercourse. Nevertheless, the majority of men age 15-24 have not had sex; of those who have, many are married (see Table 17.17.1). Relatively few young men have had multiple partners; of those who have, nearly all used condoms at last sex.

Table 17.18.1 Higher-risk sexual intercourse among youth and condom use at last higher-risk intercourse in the past 12 months: women

¹ Sexual intercourse with a nonmarital, noncohabiting partner

² Friends, family members, and home are not considered sources for condoms.

Figure 17.5 Abstinence, Being Faithful, and Condom Use (ABC) Among Young Women and Men

Note: Number of partners refers to the 12 months preceding the survey.

CDHS 2005

17.8.5 Drunkenness during Sexual Intercourse

Sexual intercourse when one or both partners are under the influence of alcohol is more likely to be unplanned than otherwise, and the partners are less likely to use condoms. Respondents who had had sex during the preceding 12 months were asked if they or their partner drank alcohol the last time they had sex, and if so, whether they or their partner were drunk. Table 17.19 shows the prevalence of sexual intercourse while drunk. The overall prevalence of sex when the respondent or partner is drunk is low, especially for young women (1 percent for women and 4 percent for men). Given the rarity of the phenomenon, differences across groups are minimal. Interestingly, most sex where alcohol is involved occurs among married respondents.

Table 17.19 Drunkenness during sexual intercourse among youth

Among all young women and young men age 15-24, the percentages who had sexual intercourse in the past 12 months while being drunk, by background characteristics, Cambodia 2005

17.8.6 HIV Testing

Young people may believe there are barriers to accessing and using many health services and facilities, particularly for sensitive concerns relating to sexual health, such as sexually transmitted infections like HIV/AIDS. Table 17.20 presents data on the percentage of sexually active youth being tested and receiving the results within the past year. Young women and men who have had sexual intercourse in the past 12 months are similarly likely to have been tested for HIV (8 percent and 10 percent, respectively). There is a clear tendency for testing rates to be higher among urban youth, youth with a secondary or higher education, youth in the highest wealth quintile, and youth living in Phnom Penh or Kandal.

Table 17.20 Recent HIV tests among youth

¹ Friends, family members, and home are not considered sources for condoms.

HIV testing was included in the 2005 CDHS to estimate HIV prevalence using a nationally representative sample of men and women age 15-49. The 2005 CDHS provides the first estimates of HIV prevalence among the male and female general population of reproductive age. Prior to the 2005 CDHS, HIV prevalence estimates have been derived primarily from sentinel surveillance of pregnant women obtaining antenatal care from public health facilities. Although the information from the ANC surveillance system has been very useful for assessing HIV levels, and especially for monitoring trends in HIV prevalence, the inclusion of HIV testing in the 2005 CDHS offers the first opportunity to obtain information on the magnitude and patterns of HIV infection in the general reproductive age population of Cambodia. Thus, the HIV prevalence data from the CDHS are expected to provide important information to plan the national response to the AIDS epidemic in Cambodia.

This chapter first presents the methodology used in conducting HIV testing as part of the CDHS survey and information on the coverage rates of HIV testing among eligible survey respondents. The chapter then discusses levels and differentials in HIV prevalence among those who were tested.

18.1 HIV TESTING PROTOCOL

The protocol for HIV testing was based on the anonymous-linked protocol developed by the Demographic and Health Surveys program. The protocol was approved by the Institutional Review Board at ORC Macro, the Atlanta office of the Centers for Disease Control National Center for HIV, STD, and TB Prevention (NCHSTP), and the National Ethics Committee for Health Research of Cambodia. Blood samples submitted for HIV testing were completely anonymous while the test result itself can be linked to the socio-demographic and behavioral data of respondents collected during the interview.

Since blood testing was performed on anonymous samples, it was not possible to inform respondents of their test results. However, a voucher listing fifty voluntary counseling and testing (VCT) facilities operating throughout the nation was distributed to all eligible respondents, whether or not they agreed to be tested for HIV. The Cambodia Office of the Centers for Disease Control and Prevention, Global AIDS Program (CDC/GAP) supplied rapid test kits that were distributed to the sixty VCT sites. The sites would offer free counseling and HIV testing to anyone presenting the voucher. Respondents were also reimbursed for transportation costs when they reached the site.

Data Collection

Blood used for laboratory testing of HIV was collected from the same finger stick performed to collect a capillary blood sample for field testing of anemia. The blood drops provided for HIV testing were collected by dripping four to five finger-prick blood drops onto a special filter paper card. A self-adhesive label printed with a randomly generated, unique, anonymous bar code number was attached to each filter paper card at the time of blood collection. No other identifier was attached to the blood sample. A second self-adhesive label printed with the same anonymous bar code number was affixed to the household questionnaire at the point where the interviewer had indicated the respondent gave voluntary consent for the laboratory testing. A third self-adhesive label printed with the same anonymous bar code number was affixed to a transmission sheet used to maintain a reliable inventory of blood samples throughout the transport procedures of samples from the field to the final destination of the laboratory.

Blood samples were dried overnight by placing the filter paper cards in a plastic box containing packets of desiccant to absorb humidity. Once blood samples were dry, each filter paper card was transferred to its own small plastic bag containing a desiccant to absorb humidity and a card to monitor humidity levels within the small plastic bag. If the humidity indicator card indicated high levels of humidity within the bag, the desiccant packet was replaced with a fresh packet to absorb the moisture. The plastic bags were specially manufactured to reduce exposure of their contents to air and moisture. Individual bags were then combined into one larger bag which also contained desiccants and a humidity indicator card; teams maintained one larger bag per each enumeration area (or cluster) interviewed. These bags, along with the questionnaires, were regularly collected by CDHS survey coordinators.

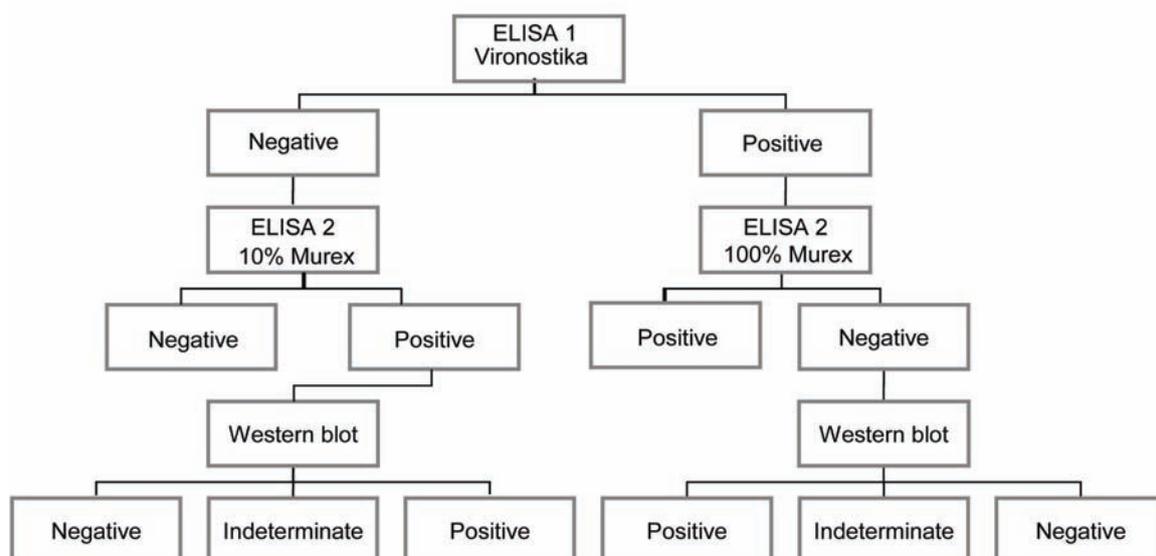

During the training session, dried blood spot (DBS) samples had been monitored over a three-week period with regard to CDHS storage practices to safeguard against humidity. Packaged according to CDHS standards, the humidity indicator cards indicated that filter paper cards could be shielded from humidity levels existent in Cambodia.

HIV Testing Procedure

Testing of DBS specimens for HIV antibodies was conducted by the National Institute of Public Health (NIPH). The Cambodia Office of the U.S. Centers for Disease Control and Prevention, Global AIDS Program (U.S. CDC/GAP) provided technical assistance and test kits to the laboratory.

The algorithm consisted of testing the specimens with ELISA 1 (Vironostika HIV Uniform II Plus 0 from Biomerieux). Vironostika was selected for the first round of testing because of the high sensitivity of its detection system. Specimens presenting an optic density less than the threshold value specified by the test kit were rendered negative; all above the threshold were rendered positive.

**Figure 18.1 HIV Testing Algorithm
National Institute of Public Health, Phnom Penh
2005 CDHS**

Specimens rendered positive using ELISA 1, as well as 10 percent of the samples rendered negative were subsequently analyzed with a second ELISA test: Murex 1.2.O. This second ELISA was chosen because of its high specificity.

All specimens rendered positive on ELISA 1 and ELISA 2 were rendered positive. All discordant samples were tested by Western Blot (New Lav Blot HIV 1) and rendered according to result of the Western Blot.

Data Processing

The NIPH was provided with the CPro program developed by ORC Macro and designed especially for the HIV-testing algorithm: CPro HIV Test Tracking System (CHTTS). As data were entered, the program automatically calculated all entries (number of blood tests, number of positives, number of negatives). Each specimen received by the laboratory had only the randomly generated, unique, anonymous bar code number that was placed on the filter paper card by the interviewer in the field. Only this code number was entered into the CPro program with the blood test result. This confidential file was maintained by NIPH until the end of the survey. Only after data entry for the entire survey was complete, and the data files at NIS had been cleaned and the data had been weighted, was a data file prepared at NIPH containing only weighting factors of respondents and a few demographic characteristics (age, sex, residence, province, education). This file was used to verify cohesion of the two data banks (the data file of questionnaires at NIS and the data file of blood samples at NIPH). To guarantee anonymity, information allowing identification of respondents by household, cluster, village, or district number were removed from the survey data files before merging the two files. The two files were merged to calculate the socio-demographic and behavioral indicators of HIV prevalence.

Quality Control

The NIPH laboratory applied its standards of internal quality control throughout the process of HIV testing for the CDHS. The U.S. CDC/GAP provides technical support to the laboratory. All samples rendered positive and 10 percent of the samples rendered negative were sent to the Atlanta laboratory of the CDC for external quality control.

18.2 Coverage of HIV Testing in the CDHS

Half of the entire sample of households selected for the 2005 CDHS were eligible for HIV testing. All women and men age 15-49 living in the 50 percent subsample of households were eligible for the HIV testing component of the CDHS. Table 18.1.1 shows the coverage rates for HIV testing among all eligible women and men by reason for not being tested, according to residence. Table 18.1.2 shows the same information separately for women and men. Response rates for providing blood samples for HIV testing were very high. In total, HIV tests were conducted for 93 percent of the 15,867 eligible respondents. The response rate is higher among women (95 percent) than among men (90 percent). Overall, 2.5 percent of men and 2.2 percent of women refused to provide blood after being interviewed for the survey.

Rural residents were somewhat more likely to be tested than their urban counterparts (94 percent and 90 percent, respectively). There are few significant differences in HIV testing coverage rates by province; response rates are lowest in Krong Preah Sihanouk/Kaoh Kong, particularly among men. Refusal rates were highest in Phnom Penh (6 percent) and Pursat (5 percent).

Table 18.1.1 Coverage of HIV testing by residence and region: all respondents

Percent distribution of de facto women and men age 15-49 eligible for HIV testing by testing status, according to residence and region (unweighted), Cambodia 2005

¹ Includes all dried blood spot (DBS) samples tested at the lab and for which there was a result (i.e., positive, negative, or indeterminate). Indeterminate means that the sample went through the entire algorithm, but the final result was inconclusive.

² Includes: 1) other results of blood collection (e.g., technical problem in the field), 2) lost specimens, 3) non corresponding bar codes, and 4) other lab results such as blood not tested for technical reason, not enough blood to complete the algorithm, etc.

Table 18.2 shows coverage rates for HIV testing by age group, education, and household wealth. If HIV status influenced participation in the testing, coverage would be expected to change with either age, education, wealth, or any other characteristics known to be associated with HIV status. In fact, coverage rates for testing in the CDHS are relatively consistent across age, among both women and men. Response rates were also fairly consistent across education levels. Men and women in the highest of the five wealth quintiles were somewhat less likely to be tested than those in other quintiles.

¹ Includes all dried blood spot (DBS) samples tested at the lab and for which there was a result (i.e., positive, negative, or indeterminate). Indeterminate means that the sample went through the entire algorithm, but the final result was inconclusive.						
² Includes: 1) other results of blood collection (e.g., technical problem in the field), 2) lost specimens, 3) non corresponding bar codes, and 4) other lab results such as blood not tested for technical reason, not enough blood to complete the algorithm, etc.						

In order to further explore whether non-response might have an impact on the HIV seroprevalence results, tables describing the relationship between participation in the HIV testing and a number of other characteristics related to HIV risk were also examined (see Tables A.8-A.11 in Appendix A). Overall, analysis of these rates show no systematic relation between participation in the test and variables associated with higher-risk of HIV infection. These results indicate that the estimated prevalence rates from the CDHS provide an unbiased measure of HIV prevalence in the general population.

18.3 HIV PREVALENCE

Results from the 2005 CDHS indicate that 0.6 percent of Cambodian adults age 15-49 are infected with HIV (Table 18.3). HIV prevalence shows no difference according to sex; both women and men have a seroprevalence of 0.6 percent. It should be borne in mind that zero prevalence estimated by the survey does not mean there are zero cases in the population. It just happened that no infected people were selected in the sample. For some background and sexual behavioral characteristics and some provinces, due to the low HIV prevalence in the population in those categories, and the relatively small sample size, it is difficult to estimate precisely the prevalence.

Table 18.3 also shows that HIV prevalence levels rise with age, peaking among women in their late 20s and among men in their 30s. Young men and women age 15-24 have a lower seroprevalence rate (0.0 percent among those age 15-19 and 0.4 percent among those age 20-24) than older men and women. Prevalence rates then remain constant beginning with the 25-29 year age group.

Table 18.3.1 HIV prevalence by age: women

Total age 15-49	0.6	0.4	0.8	14,703	14,702

HIV Prevalence by Socioeconomic Characteristics

As Table 18.4 shows, marital status is closely related to HIV prevalence. Women and men who are widowed and those who are divorced or separated have significantly higher rates than those who are married or living together. HIV rates are lowest for respondents who have never been in union. Urban residents have a higher risk of HIV infection (1.4 percent) than rural residents (0.4 percent). Prevalence levels are highest in Phnom Penh (1.7 percent) and Krong Preah Sihanouk/Kaoh Kong (1.3 percent). The lowest overall prevalence is found in Mondol Kiri/Rattanak Kiri and Svay Rieng (0.0 percent).

HIV infection levels show no clear pattern according to education levels. Women with no schooling have slightly higher prevalence rates than those with higher education. On the other hand, men with secondary or higher education have higher prevalence rates than those with less education. Employment in the past 12 months is also related to HIV levels among men but not women; those who are employed being more likely than the unemployed to be infected. Particularly among men, those who were unemployed during the 12-month period prior to the survey are heavily concentrated in the younger age groups where HIV levels are quite low. This helps to explain why none of the men in this category were HIV positive.

Both women and men in the highest wealth quintile have higher rates of HIV infection than those in other wealth quintiles.

HIV Prevalence by Other Demographic Characteristics

Table 18.5 looks at how HIV rates relate to two measures of mobility. The results indicate that women who have slept away from their homes at least five times in the past year have a seroprevalence rate more than three times the national figure (2.0 percent). Similarly, women who were away from their homes for more than a month at a time also had an elevated HIV prevalence (1.5 percent). The pattern of mobility and HIV prevalence among men is not as clear.

Notably, HIV rates are somewhat higher among women who received antenatal care at a public health facility in the three-year period prior to the survey (0.8 percent). HIV prevalence among women who are currently pregnant is 0.3 percent, roughly half the level found among nonpregnant women.

Demographic characteristic	Women		Men		Total	
	Percentage HIV positive	Number	Percentage HIV positive	Number	Percentage HIV positive	Number
Times slept away from home in past 12 months						
None	0.4	5,156	0.7	3,319	0.6	8,475
1-2	0.8	1,850	0.5	1,670	0.7	3,520
3-4	0.2	621	0.3	758	0.3	1,379
5+	2.0	403	0.8	901	1.2	1,304
Time away in past 12 months						
Away for more than one month	1.5	557	0.3	844	0.8	1,401
Away only for less than one month	0.7	2,318	0.6	2,487	0.6	4,806
Not away	0.4	5,164	0.7	3,325	0.6	8,488
Currently pregnant						
Pregnant	0.3	475	na	na	na	na
Not pregnant or not sure	0.6	7,572	na	na	na	na
ANC for last birth in the past 3 years

No ANC/no birth in past 3 years	0.5	6,583	na	na	na	na
Total	0.6	8,047	0.6	6,656	0.6	14,703

Note: Total includes 24 individuals for whom the number of times slept away from home in past 12 months is unknown and 8 individuals for whom time spent away in past 12 months is unknown.
na = Not applicable

HIV Prevalence by Sexual Risk Behavior

Table 18.6 presents HIV prevalence rates by sexual behavior indicators among respondents who have ever had sexual intercourse. In reviewing these results, it is important to remember that responses about sexual risk behaviors may be subject to reporting bias. Also, sexual behavior in the 12 months preceding the survey may not adequately reflect lifetime sexual risk.

Table 18.6 HIV prevalence by sexual behavior

Percentage HIV positive among women and men age 15-49 who ever had sex and were tested for HIV, by sexual behavior characteristic, Cambodia 2005

Sexual behavior characteristic	Women		Men		Total	
	Percentage HIV positive	Number	Percentage HIV positive	Number	Percentage HIV positive	Number

Note: Condom refers to male condom. Total includes 164 individuals for whom age at first sex is unknown, 11 individuals for whom condom use is unknown, 6 individuals for whom condom use at last sexual intercourse is unknown, 6 individuals for whom number of sexual partners in past 12 months is unknown, and 58 individuals for whom number of lifetime partners is unknown. Figures in parentheses are based on 25-49 unweighted cases. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.

na = Not applicable

¹ Sexual intercourse with a partner who neither was a spouse nor who lived with the respondent

² A partner who neither was a spouse nor who lived with the respondent, among the last three partners in the past 12 months

³ Includes men who report having a prostitute for at least one of their last three sexual partners in the past 12 months

For women, there appears to be a pattern of higher HIV prevalence with sexual debut at earlier ages while the age at which men initiated sex appears to be unrelated to their HIV status. Respondents are considered to have had a higher-risk sexual encounter if they had intercourse with a nonmarital, noncohabiting partner. Table 18.6 shows that both women and men who had ever had sex but reported not having had sexual intercourse in the past 12 months are more likely to be HIV-infected than those who were sexually active during that time period. The prevalence among women who reported not having had sexual intercourse in the past 12 months is 2.1 percent and among men it is 3.0 percent, compared with 0.8 and 0.9 percent respectively among women and men who have ever had sex. This is a surprising finding that warrants further attention.

The results in Table 18.6 suggest that HIV risk rises directly with the number of lifetime sexual partners that an individual has. Individuals with 10 or more lifetime partners have a seroprevalence rate five times the national figure (3.0 percent).

Finally, among men, those who said that they paid for sex in the 12 months preceding the survey have an HIV prevalence twice that of those who reported not paying for sex.

18.4 HIV PREVALENCE AMONG YOUTH

Tables 18.7 and 18.8 present HIV prevalence by background characteristics and by sexual behavior characteristics related to HIV risk among young women and men age 15-24. Table 18.7 shows that young women and men have low HIV prevalence rates. Women age 15-24 are estimated to have HIV rates of 0.3 percent and men age 15-24 are estimated to have HIV rates of 0.1 percent. There is little meaningful difference in these figures by background characteristics.

Table 18.8 presents HIV prevalence among young men and women age 15-24 who have ever had sex. This table shows that HIV rates are slightly higher among young men and women who have ever had sex, compared with all young men and women. Women age 15-24 who have ever had sex are estimated to have HIV rates of 0.6 percent and men age 15-24 who have ever had sex are estimated to have HIV rates of 0.3 percent.

18.5 HIV PREVALENCE BY OTHER CHARACTERISTICS RELATED TO HIV RISK

Table 18.9 presents HIV prevalence by other characteristics related to HIV risk among women and men who have ever had sex. The table shows that those with sexually transmitted infection (STI) or STI symptoms in the past 12 months have significantly higher rates of HIV infection than those with no history or symptoms, particularly among men. Women with a history of STI infection are almost three times as likely to be infected by HIV (1.9 percent) as those without a history of STI infection (0.7 percent). Men with a history of STI infection are almost twenty times as likely to be infected by HIV (13 percent) as those without a history of STI infection (0.7 percent).

Table 18.9 HIV prevalence by other characteristics

Percentage HIV positive among women and men age 15-49 who ever had sex and who were tested for HIV, by whether had an STI in the past 12 months and by prior testing for HIV, Cambodia 2005

Characteristic	Women		Men		Total	
	Percentage HIV positive	Number	Percentage HIV positive	Number	Percentage HIV positive	Number
Sexually transmitted infection in past 12 months						
Had STI or STI symptoms	1.9	523	13.0	91	3.5	614
No STI, no symptoms	0.7	4,976	0.7	4,335	0.7	9,311
Prior HIV testing						
Ever tested	3.1	693	2.3	876	2.7	1,569
Received results	3.3	643	2.3	802	2.8	1,445
Did not received results	0.0	50	2.5	74	1.5	124
Never tested	0.5	4,777	0.6	3,558	0.5	8,335
Total	0.8	5,548	0.9	4,453	0.9	10,000

Note: Total includes 75 individuals for whom sexually transmitted infection is unknown and 96 individuals for whom prior HIV testing is unknown.

The table also shows that the women and men who have been tested for HIV have higher rates of HIV infection than those who have never been tested. Among women, 3.1 percent who had been tested for HIV prior to the survey were HIV positive compared with 0.5 percent who had not been tested previously; among men 2.3 percent who had been tested for HIV prior to the survey were HIV positive compared with 0.6 percent who had not been tested previously.

Table 18.10 also shows the relationship between prior HIV testing status and HIV prevalence. Among the men and women who tested positive for HIV as part of the CDHS, 42 percent had been tested for HIV at some time before the CDHS interview, and had received their results. Among those who were found to be HIV negative, only 11 percent had been tested for HIV at some time before the CDHS interview and received their results. This would indicate that a significant proportion of those who are HIV positive already know their status, which is an important first step to preventing widespread infection.

Table 18.10 Prior HIV testing by HIV status

Percent distribution of women and men age 15-49 who tested HIV positive and who tested HIV negative by HIV testing status prior to the survey, Cambodia 2005

HIV testing prior to the survey	Women		Men		Total

Number of respondents	49	7,998	42	6,614	91	14,613

Note: Figures in parentheses are based on 25-49 unweighted cases.

18.6 HIV PREVALENCE AMONG COUPLES

Over 3,600 cohabiting couples were tested for HIV in the 2005 CDHS. Results shown in Table 18.11 indicate that, for 99 percent of cohabiting couples, both partners tested negative for HIV. Half of the majority of the remaining couples (0.5 percent) are discordant, that is, one partner is infected and the other is not; most commonly it is the man who is HIV positive while the woman is not. Rates of discordant couples are higher in urban areas (1.6 percent) than in rural areas (0.4 percent).

Table 18.11 HIV prevalence among couples

Percent distribution of couples living in the same household, both of whom were tested for HIV, by the HIV status, according to background characteristics, Cambodia 2005

Note: Table based on couples for which a valid test result (positive or negative) is available for both partners. Figures in parentheses are based on 25-49 unweighted cases.

One of the most serious impacts of the HIV/AIDS epidemic is the dramatic increase in the number of children orphaned and put at risk by the death or chronic illness of one or more of the adults in their household. Deprived of these adults' protection, such children are at increased risk of trafficking, violence, exploitation, and other forms of abuse.

Goals have been established aimed at developing policies and strategies to support orphans and children at risk by ensuring their access to education, proper nutrition, and health and social services. The 2005 Cambodia DHS gathered data aimed at measuring the condition of at-risk children, some of which are presented in this chapter.

19.1 ORPHANHOOD AND CHILDREN'S LIVING ARRANGEMENTS

Because the family is the primary safety net for children, any strategy aimed at protecting children must place a high priority on strengthening family capacities to care for children. It is therefore essential to identify orphaned children and find out whether those who have one or both parents living are living with either or both surviving parents. Table 19.1 presents these two types of information for children under age 18, according to selected background characteristics.

The data show that 79 percent of Cambodian children under the age of 18 live with both their parents. This proportion declines slightly with age, from a high of 89 percent at age 0-1 year and 82 percent at age 5 to 9 years, to 70 percent at age 15 to 17 years. The results show practically no difference according to the child's sex. The proportion of children living with both parents is somewhat higher in rural areas (80 percent) than in urban areas (76 percent). In addition, 11 percent of children under age 18 live with their mother only, whether their father is alive or deceased, and 2 percent live with their father only. Seven percent do not live with either parent.

Overall, 9 percent of children under age 18 have lost their father and/or mother: 1 percent have lost both parents, 7 percent have lost their father, and 3 percent have lost their mother. Because a parent's risk of dying increases with time, the proportion of children who have lost their father and/or mother increases significantly with the age of the child, from 2 percent at ages 0 to 1 year, to 3 percent at ages 2 to 4 years, to 7 percent at ages 5 to 9 years. These proportions jump to higher levels among children ages 10 to 14 (12 percent) and 15 to 17 (16 percent).

Table 19.1 Children's living arrangements and orphanhood

Percent distribution of children under age 18 by children's living arrangements and survival status of parents, the percentage of children not living with a biological parent, and the percentage of children with one or both parents dead, according to background characteristics, Cambodia 2005

Background characteristic	Living with both parents	Living with mother but not father		Living with father but not mother		Not living with either parent				Missing information on father/mother	Total	Percentage with one or both parents dead	Number of children
		Father alive	Father dead	Mother alive	Mother dead	Both alive	Only father alive	Only mother alive	Both dead

19.2 SCHOOL ATTENDANCE

Access to education is considered an “essential service” and is included among the key components of national responses to guarantee that children who have been orphaned have access to services on an equal basis with other children. Table 19.2 assesses whether children who have been orphaned are educationally disadvantaged in relation to other children. The results are presented for children between the ages of 10 and 14 years, which is the age group at which school attendance is generally assumed for all children.

Table 19.2 School attendance by survivorship of parents

For children 10-14 years of age, the percentage attending school by parental survival according to background characteristics, Cambodia 2005

Background characteristic	Percentage attending school by survivorship of parents				Ratio ¹
	Both parents dead		Both parents alive and living with at least one parent		
	Percentage	Number	Percentage	Number	
Sex					
Male	74.1	57	92.5	4,254	0.8
Female	78.2	56	90.8	4,253	0.9
Residence					
Urban	(75.4)	31	92.4	1,100	0.8
Rural	76.4	83	91.5	7,408	0.8
Total	76.1	114	91.6	8,508	0.8

Note: Table is based on de jure household members, i.e., usual household members. Figures in parentheses are based on 25-49 unweighted cases.
¹ Ratio of the percentage with both parents dead to the percentage with both parents alive and living with a parent.

The data show a clear relationship between parent survivorship and school attendance of children ages 10 to 14. Whereas 92 percent of children whose parents are both alive and who are living with one of their parents attend school, only 76 percent of children who have lost both parents attend school. The ratio of school attendance among orphaned to non orphaned children is less than 1, indicating an educational disadvantage among orphans, in relation to other Cambodian children.

19.3 BASIC MATERIAL NEEDS

The 2005 CDHS enquired whether children age 5-17 possessed three basic needs: shoes, two sets of clothing, and a blanket. Nationally, 85 percent of children reported having a pair of shoes, 94 percent reported having two sets of clothing and 75 percent reported having a blanket (Table 19.3). Overall, 69 percent of children age 5-17 were reported to possess all three basic needs. The percentage of children having all three basic needs was highest in Phnom Penh (86 percent) and Krong Preah Sihanouk/Kaoh Kong (85 percent) and lowest in Kampong Chhnang (39 percent). Not surprisingly, children from the wealthiest households, are more likely to have all three basic material needs (91 percent) than children from the poorest households (47 percent).

Table 19.3 also shows the same information by orphanhood status, comparing the children age 5-17 for whom one or both of their natural parents has died, to children for whom both natural parents are living. In general, children who are orphans do as well as non-orphans with regard to the provision of these three basic needs. Orphans age 5-9 years and those living in Banteay Mean Chey and Prey Veng do slightly less well than the non-orphans in the same groups.

Table 19.3 Possession of basic material needs by orphanhood status

Among children age 5-17 years, the percentage possessing three minimum basic material needs, the percentages of orphaned children and non-orphaned children who possess all three basic material needs, and the ratio of the percentage for orphaned children to the percentage for non-orphaned children, according to background characteristics, Cambodia 2005

Background characteristic	Among children 5-17 years of age percentage possessing:					Percentage possessing all three basic needs ¹ by orphanhood status				Ratio ²

¹ Shoes, two sets of clothing, a blanket

² Ratio of the percentage for orphaned children (i.e. with one or both parents deceased) to the percentage for non-orphaned children (i.e. with neither parent deceased)

19.4 SEPARATION OF SIBLINGS

Once a child has lost one or both parents, it is not an uncommon strategy for the living adults responsible for the child to reduce their own burden of care to disburse the orphaned siblings to different households, lessening the burden of care for any one household. This in turn may cause significant stress to the siblings who are consequently separated from one another. Table 19.4 presents the percentage of orphans who are not living with all of their siblings who are under the age of 18. Once a child has reached the age of 18 he or she is considered to be an adult and may be living on his or her own.

The 2005 CDHS found that 17 percent of children who have lost one or both parents are not living with all their siblings who are also under the age of 18 years. It is more common for orphans to be separated from their siblings when it is either their mother (24 percent) or both parents who have died (28 percent), compared with if the father has died (14 percent). Over 30 percent of orphans living in Kampong Speu and Takeo are separated from his/her siblings, as compared with less than 3 percent in Battambang/Krong Kep.

19.5 SUCCESSION PLANNING

Strengthening family capacities to support and protect orphans is essential. Identifying someone who will care for a child if his caregiver dies or falls ill is one way to ensure a better future for children.

In Cambodia, 52 percent of women and men reported being primary caregivers to children under age 18, irrespective of whether these children were their own (Table 19.5). This proportion increases significantly with the age of the respondent, from 15 percent among respondents ages 15 to 19, to 75 percent among those age 40 to 49. Far more women (62 percent) than men (27 percent) report being a child's primary caregiver. Caregiver status is inversely related to education level: women and men with a higher level of education are less likely to be a caregiver (38 percent) than those with no schooling (67 percent).

Among these primary caregivers, 74 percent said that they had made arrangements to have someone care for these children in the event of their own illness or death. Although men are far less likely to be a primary caregiver than women, the proportion of male caregivers who have made succession arrangements is higher (90 percent) than female caregivers (72 percent). The percentage of caregivers who have made arrangements is also somewhat higher in rural areas (75 percent) than in urban areas (70 percent). It is highest in Takeo, Pursat, and Kampong Chhnang (between 98 and 100 percent) and lowest in Kampot/Krong Kep (33 percent).

Table 19.4 Orphans not living with siblings

Among orphans under age 18 years who have one or more siblings under age 18 years, the percentage who do not live with all their siblings under age 18, by background characteristics, Cambodia 2005

Note: Table is based on de facto household members, i.e. who slept in household the night preceding the interview

19.6 DISPOSSESSION OF PROPERTY

Dispossession of property can worsen the vulnerability of people who care for children and the children themselves. It is therefore important to ensure that inheritance laws include enforcement mechanisms to ensure the right of women and children to inherit property after the death of a husband or father (UNICEF, 2005).

Table 19.6 presents the proportion of women who were or are widows (ever-widowed) and the prevalence of dispossession. Altogether, 6 percent of women surveyed were ever-widowed. This proportion naturally increases with the age of the woman, from 2 percent at ages 20 to 29, to 16 percent at ages 40 to 49. Women with no schooling (10 percent) are more likely to have ever been widowed than women with secondary or higher schooling (2 percent).

Forty-five percent of all ever-widowed women reported that their husbands did not have any possessions or assets; therefore, Table 19.6 presents the percentage of ever-widowed women who were dispossessed of their property after the death of their husband among those women whose husbands had any possessions. Overall, 8 percent of ever-widowed women reported that their late husbands' possessions went to someone other than themselves, among those women whose husbands did have some possessions, assets, or property.

Table 19.6 Widows dispossessed of assets and valuables				
Percentage of de facto women age 15-49 who have been widowed, and the percentage of widowed women who reported that most of their late husbands' possessions went to someone other than themselves, among widows whose husbands had possessions, Cambodia 2005

Note: Table is based on de facto women, i.e., who slept in the household the night preceding the interview. Figures in parentheses are based on 25-49 unweighted cases. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.

¹ Dispossession of assets indicates that the late husband's property, assets, or valuables went to someone other than the respondent.

² Excluding women who reported their husbands had no property, assets, or valuables.

To examine the status of women in Cambodia, the CDHS 2005 included a special women's status module of questions. The study of women's status and empowerment is important on its own, but takes on a special significance in conjunction with the study of demographic and health outcomes. Women are the targets directly or indirectly (as the caretakers of their children) of a number of population, health, and nutrition programs. The constraints that women face in learning about, accessing, and utilizing these and other developmental programs are inherently tied to their status in society, as well as in their home.

Recognizing the multifaceted nature of women's status and empowerment, the women's status module included questions that explore various aspects of women's status and empowerment, including women's role in selecting their spouse, degree of participation in household decision-making, spousal communication, control over household income and expenditures, ownership of assets, degree of isolation from natal families, participation in civil society, and knowledge of various laws related to women's rights. The module also contained a set of three questions that explore women's beliefs about gender roles. Information from the women's status module is designed to be complementary to the marriage, education, and employment information discussed earlier.

The women's status module was implemented in one-fourth of the households included in the CDHS 2005 sample. Thus, the women's status questions were asked of women in one out of every four selected sample households and yielded a total of 4,201 completed interviews.

20.1 MARRIAGE PATTERNS

Marriage patterns are greatly influenced by culture and tradition, and their study often yields important insights into women's status and empowerment in society, as well as in their marriage. At the individual level, various aspects of a woman's marriage are likely to affect the amount of autonomy and control she has in her married life.

Spouse Selection

The CDHS 2005 asked ever-married women how long they had known their husband before their marriage and who chose their husband for them. For women who were married more than once, these questions refer to their current or most recent husband only. Table 20.1 shows the length of time women knew their husband before marriage, as well as the persons involved in the choice of the husband by background characteristics.

Eighteen percent of ever-married women in Cambodia met their husband for the first time at the time of marriage. An additional 9 percent knew their husband for less than one month before their marriage. These data suggest that one quarter of all ever-married women were married to relative strangers. However, it should be noted that this figure is fully half of the corresponding proportion observed in the 2000 CDHS. The likelihood that a woman met her husband for the first time at the time of marriage is considerably greater among women age 30 or older (about 21 percent) than among younger women (8 percent among 15-19 year olds and 12 percent among 20-24 years olds); this age-related observation continues the trend observed in 2000, which suggests that this practice may be declining over time.

Table 20.1 Choice of spouse

Percent distribution of ever-married women by length of time they knew their husband before marriage and degree of involvement in spouse selection, according to background characteristics, Cambodia 2005

Background characteristic	Length of time woman knew husband before marriage						Person who chose husband							Number of women	
	Met on wedding day	Knew less than 1 month	Knew less than 1 year	Knew 1 year or more	Knew since childhood	Total	Respon- dent	Respon- dent and hus- band	Respon- dent with some- one else	Respon- dent's family	Hus- band or his family choose respon- dent	Some- one else	Forced by hus- band		Total

Table 20.1 also shows that few women choose their own husband. Only 19 percent of ever-married women chose their husband (chose alone or the respondent and her husband chose each other jointly). In addition, 29 percent of women chose their husband jointly with someone else. The remaining majority of women (52 percent) did not participate at all in the choice of their husband. For 11 percent of all ever-married women, the husband was chosen by his own family only.

Urban women (19 percent) are more likely than rural women (10 percent) to have chosen their own husband. By region, self-choice of spouse is most common in Siem Reap, where 36 percent of women say that they chose their own husband. Women in Takeo are least likely to have chosen their own husband.

Table 20.2 shows data on interspousal age and education differences by background characteristics for currently married women. Currently married Cambodian women are, on average, only 2.9 years younger than their husband. Notably, 13 percent of women are at least two or more years older than their husband, and another 25 percent are about the same age (husband younger or older by no more than one year). Only 8 percent of all currently married women are married to men who are ten or more years older than them. The mean spousal age difference is higher for currently married women age 15-19 (five years) than for older women.

Table 20.2 Differences in age and education between spouses

Percent distribution of currently married women by interspousal age differences and by difference in years of education, and mean age and educational differences, according to background characteristics, Cambodia 2005

	Interspousal age difference					Total	Mean difference in age (husband-wife)	Interspousal education differential				Total	Mean difference in years of education (husband-wife)	Number of women
	Wife older by 2+ years	About the same age	Husband older than wife by:					Husband better educated	Wife better educated	Both have equal education	Neither educated

Table 20.2 also shows differences in education between currently married women and their husbands by background characteristics. Men are most likely to be married to women who have fewer years of education than they do. Overall, 55 percent of men have more education than their wife and 20 percent have less education than their wife.

20.2 INTERSPOUSAL COMMUNICATION

The degree of interspousal communication provides insight into the nature of women's current marital relationships. In addition, marriages based on a free flow of communication are likely to be more conducive to the promotion and adoption of several of the demographic and health behaviors and outcomes of interest. Table 20.3 shows the percentages of women who said that they communicated often with their spouse on specific topics.

Background and marital characteristic	Percentage who talk with spouse often about:					None of the topics	Number of currently married women
	Things that happen at work/farm	Things that happen at home	What to spend money on	Things that happen in community	All of the four topics		
Age

10 years or more	22.6	31.4	36.4	5.9	3.9	55.1	1,297
Married more than once	20.3	35.5	40.1	5.7	3.9	51.5	195
Total	21.8	29.9	35.9	5.3	3.4	55.8	2,508

Few currently married women (3 percent) talk often with their husband about all of the listed topics, while 36 percent talk often with their husband about what money should be spent on, 30 percent talk often about things that happen at home, and 22 percent talk often about things that happen at work or on the farm. Overall, 56 percent of currently married women say that they do not often talk to their husband about any of the four topics. Overall, the most striking feature of these data is the limited amount of communication between husbands and wives on these selected topics in all subgroups of the population.

20.3 DECISIONMAKING WITHIN HOUSEHOLDS

To assess women's role in household decisionmaking, the CDHS 2005 asked women who in their family usually has the final say on six different types of decisions: visits to family, friends, or relatives; making household purchases for daily needs; making large household purchases; whether the respondent should work to earn money; whether to use contraception; and the respondent's own health care. In addition, women who had one or more living children were also asked who in their household usually had the final say on decisions about children's schooling, what to do if the child falls sick, and whether to have another child.

Table 20.4 shows that currently married women almost always have the final say, alone or jointly, in all of the listed decisions. Almost all currently married women have a say, alone or jointly, in final decisionmaking about visits to family or relatives (93 percent), daily household purchases (95 percent), and the woman's own health care (97 percent). Few women who are not currently married have a say in household decisionmaking, with the exception of the woman's own health care (81 percent).

Household decision	Respondent only	Jointly with husband	Jointly with someone else	Husband only	Someone else only	Decision not made/not applicable	Missing	Total	Number of women
CURRENTLY MARRIED WOMEN

Table 20.5 shows women's participation in decisionmaking according to background characteristics. Almost all women have a say, either alone or jointly, in their own health care. Slightly less than one-third of women (31 percent) have a say in all six of the decisions listed, while 6 percent have a say in none of the decisions listed. Among women with children, almost all have a say in what to do if their child falls sick (97 percent) and a high percentage have a say in their child's schooling (84 percent) and whether or not to have another child (85 percent).

Table 20.5 Women's participation in household decisionmaking

Percentage of women who say that they alone or jointly have the final say in specific decisions, according to background characteristics, Cambodia 2005

20.4 ATTITUDES TOWARD GENDER ROLES

An important aspect of women's status and empowerment is the belief in the ideal of gender equality in roles and rights in society, as well as in the home. The CDHS 2005 explores women's acceptance of unequal gender roles by asking three different sets of questions related to gender roles. The first set seeks to determine women's agreement or disagreement with different statements about gender roles in the household and about education for male and female children. The second set of questions asks women about their attitudes toward wife beating. Attitudes that see the beating of wives by husbands as justified are indicative of women's lower status both absolutely and relative to men. Although such attitudes do not necessarily signify approval of men beating their wives, they do signify women's acceptance of norms that give men the right, in this case, to discipline women with force. The third set of questions explores the issue of sexual rights of wives. Beliefs about whether and when a woman can refuse sex to her husband reflect issues of gender equity with regard to sexual rights and bodily integrity. Besides yielding an important measure of empowerment, the information about women's attitudes toward sexual rights will be useful for improving and monitoring reproductive health programs that depend on women's willingness and ability to control their own sexual lives.

Gender Roles in the Household

The CDHS 2005 explored women's beliefs about gender-egalitarian roles for husbands and wives in the household by eliciting information on women's agreement or disagreement with the following statements:

1. The important decisions in the family should be made by the men of the family.
2. If the wife is working outside the home, then the husband should help her with household chores.
3. A married woman should not be allowed to work outside the home even if she wants to.
4. The wife has a right to express her opinion if she disagrees with what her husband is telling her.
5. It is acceptable for a man to have sex outside the marriage.
6. A wife should tolerate being beaten by her husband in order to keep the family together.
7. It is better to educate a son than a daughter.

Disagreement with statements 1, 3, and 5-7 and agreement with statements 2 and 4 are considered to be the responses most consistent with a greater acceptance of egalitarian gender roles. Table 20.6 shows the percentage of women who gave responses consistent with gender-egalitarian roles by background characteristics. Note that to present the data consistently (i.e., in terms of disagreement only), statements 2 and 4 are listed in the table in terms of their converse.

The percentage of women giving gender-egalitarian responses varies by statement. Fifty-five percent of women disagree with the statement that it is better to educate a son than a daughter. Eighty-nine percent of women disagree with the statement that it is acceptable for a man to have sex outside the marriage. Although 91 percent of women agree that a wife has a right to express her opinion even if she disagrees with her husband, only 47 percent disagree with the statement that men should be making the important decisions in the household. About 42 percent of women feel that married women should not be allowed to work outside the home.

Table 20.6 Gender-related attitudes

Percentage of women who disagree (reflecting gender-egalitarian ideas) with specific statements about gender-based roles, by background characteristics, Cambodia 2005

Background characteristic	Percent of women who disagree with the statement:							Number of women	Mean number of statements with which there is disagreement
	Important decisions should be made by men	Husband should not help with household chores	Married women should not be allowed to work	Wife does not have the right to express her opinion	Acceptable for a man to have extramarital sex	Wife should tolerate beatings to keep family together	Better to educate sons than daughters

Women's Agreement with Reasons for Wife Beating

To assess women's degree of acceptance of wife beating, the CDHS 2005 presented the following scenario to all women: "Sometimes a husband is annoyed or angered by things which his wife does. In your opinion, is a husband justified in hitting or beating his wife in the following situations. . . ." The four situations presented to women for their opinion were if she argues with him,

if she goes out without telling him, if she neglects the children, and if she refuses to have sex with him. The first four columns in Table 20.7 show how acceptance of wife beating varies for each reason. The fifth column gives the percentages of women who feel that a husband is justified in beating his wife for at least one of the given reasons.

Background characteristic	Percentage who agree with specific reasons:				Percentage who agree with at least one reason	Percentage who agree with none of the reasons	Number of women
	Argues with him	Goes out without telling him	Neglects the children	Refuses sexual relations			
Age							
15-19	23.8	27.7	37.4	9.5	48.9	51.1	925

Half of women (55 percent) agree with at least one reason to justify a husband beating his wife. Women are least likely to consider that a husband is justified in beating his wife if she refuses to have sexual relations with him. Women are most likely to consider that a husband is justified in beating his wife if she neglects the children (45 percent). Agreement with any of the reasons justifying wife beating tends to increase with the number of living children. In every subgroup of population women are most likely to agree that a husband is justified in beating his wife if she neglects the children.

Women's Agreement with Reasons for Refusing Sexual Relations

The extent of control women have over when and with whom they have sex has important implications for demographic and health outcomes. To measure women's agreement with a woman's right to refuse her husband sex, the CDHS 2005 asked respondents whether a wife is justified in refusing to have sex with her husband under four circumstances: she is tired or not in the mood, she has recently given birth, she knows her husband has sex with other women, and she knows her husband has a sexually transmitted infection (STI) or AIDS. These four circumstances for which women's opinions are sought were chosen because they are effective in combining women's rights and women's health issues. Table 20.8 shows the percentage of women who say that women are justified in refusing sex to their husband for specific reasons by background characteristics. Note that, unlike in the case of the previous indicator of empowerment, this indicator is positively related to empowerment: the more reasons women agree with, the higher is their "empowerment" in terms of their belief in women's sexual rights.

The majority (75 percent) of women age 15-49 in Cambodia agree that women can refuse sex to their husband for at least one of the given reasons. Agreement with all four reasons is lowest among the youngest women, among those who have never been married, and among those who have never had children; otherwise, there is minimal variation by background characteristics other than region.

Table 20.8 Women's agreement with reasons for refusing to have sexual relations with husband

Percentage of women who agree with specific reasons justifying a wife refusing to have sexual relations with her husband, by background characteristics, Cambodia 2005

Background characteristic	Percentage who agree with specific reasons:				Percentage who agree with at least one reason	Percentage who agree with none of the reasons	Number of women
	Tired, not in mood	Gave birth recently	Knows husband has sexual relations with other women	Knows husband has STI

20.5 SUPPORT FROM BIRTH FAMILY

The knowledge that their birth family is close by and willing to provide support if needed can be an important source of empowerment for women. To assess women's perception of support from their family, the CDHS 2005 asked women whether any members of the birth family were living close by, and whether women had anyone in the family who could a) give them shelter for a few nights if they needed it and b) give them financial support if needed. Table 20.9 shows the percentages of women who have support from their family measured in terms of these three indicators for all women and for currently married, widowed, and separated women by coresidence with in-laws.

Table 20.9 Birth family interaction and support

Percentage of women who have a birth family member living close by and percentage with different aspects of birth family support among all women and among married, separated, and widowed women by coresidence with in-laws, Cambodia 2005

Residence and support of birth family	All women	Married, separated, widowed	
		Living with in-laws	Not living with in-laws
Has birth family-member living close by	53.5	80.0	79.4
Support from birth family			
Has someone who can give shelter	58.7	91.8	86.4
Has someone who can give financial support	44.8	64.4	66.5
Number	4,201	257	2,468

More than half (54 percent) of all women in Cambodia live close to one or more members of their birth family, over half (59 percent) have one or more family members who would give them shelter if needed, and less than half (45 percent) have someone who can give them financial support if they needed it. These proportions are all considerably higher for women who are currently married, separated, or widowed and do not differ much by whether these ever-married women are residing with in-laws.

20.6 FINANCIAL EMPOWERMENT

Direct access to financial resources is likely to be an important cause of and contributor to women's status and empowerment. However, direct access to financial resources can take many different forms, including own earnings, access and use of credit, control over household income, or asset ownership and control. In this section, several different indicators of financial empowerment other than earnings control (which has been discussed earlier) are considered. Specifically, ownership of assets, familiarity with the credit schemes that give loans to women, and control of income for specific types of expenditures are examined.

Table 20.10 shows the proportion of all women who own, alone or jointly with someone else, each of six different types of assets: land; current house or dwelling; some other house, apartment, or dwelling; jewelry or gems; livestock; and car or motorbike. Further, for women who own an asset alone, the table also shows the proportion who can sell the asset without permission from someone else. Although having the right to even co-own valuable assets can be an important indicator of women's status in a given society, for assets to be a source of financial empowerment for women, it is important that women know that they can sell the asset if they ever need to without first having to ask someone else for permission.

About two-thirds of Cambodian women are owners or co-owners of the dwelling they reside in (69 percent) and a similar proportion own some land (60 percent). In addition, about half are owners or co-owners of livestock and jewelry or gems, and about one quarter (27 percent) of a car or motorbike. Few own alternative dwellings, houses, or apartments. The majority of women who own an asset alone can sell the asset without permission. The only asset that women are somewhat less likely to be able to sell without permission, even if they own it alone, is land. Even so, 65 percent of women who own land alone can sell it without permission.

Table 20.10 Ownership of assets

Percentage of women who own specific types of assets alone or jointly, and among those who own the asset alone, percentage who can sell the asset without permission, by type of asset, Cambodia 2005

Asset	Percentage of women who own asset:			Number of women	Of those who own asset alone, percentage who can sell without permission	Number of women who own asset alone
	Alone	Jointly	Total			
Land	13.6	46.5	60.1	4,201	64.7	570
Dwelling living in	9.3	60.0	69.3	4,201	73.3	393
Other dwelling	0.3	4.1	4.3	4,201	*	11
Jewelry or gems	20.6	30.1	50.7	4,201	82.1	867
Livestock	6.6	43.3	49.9	4,201	81.7	276
Car or motorbike	3.9	23.2	27.1	4,201	89.7	165

Note: An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.

A collection of different summary indicators of women's financial autonomy, including asset ownership, are presented together in Table 20.11. The specific indicators included are the following:

a) Two indicators of asset ownership: the percentage of women who own alone or jointly at least one of the six assets in Table 20.10 and the percentage of women who own alone and can sell at least one of these assets

b) Two indicators of exposure to credit programs: the percentage of women who know of any programs in their area of residence that give loans to women to start or expand a business of their own and the percentage of women who have ever applied for or taken such a loan

c) Two indicators of women's control over income for specific sets of expenditure items: percentage of women who control the money needed to buy one or both of the following household items: perishable foods and staple foods, and the percentage of women who control the money needed to buy one or more of the following personal items for themselves: clothes, any kind of medicinal care, or toiletries such as lipstick and perfume.

Given the relatively high ownership of assets by women shown in Table 20.10, it is not surprising that 82 percent of women in Cambodia own or co-own at least one of the six assets listed earlier. However, only one-quarter of women own at least one asset alone that they can sell without permission. Exposure to and use of any credit programs for women is limited. While 54 percent of women know of any credit programs for women, only 15 percent have ever taken a loan to start or expand a business. An examination of women's control over household expenditure reveals that 63 percent of women control the money required for household items, namely, perishable or staple food items, and 66 percent control money for one or more personal items.

Table 20.11 Economic autonomy

Percentage of women who own assets, are exposed to modern financial institutions, and have control over income, by background characteristics, Cambodia 2005

Background characteristic	Asset ownership		Exposure to modern financial institutions		Control over income		Total
	Owens at least one asset alone or jointly	Owens at least one asset alone and can sell it without permission	Knows about credit programs	Ever applied for/taken a loan	Controls money for at least one household item	Controls money for at least one personal item

20.7 INVOLVEMENT WITH CIVIL SOCIETY

Involvement in civil society is not only a source of empowerment for women, but it is also a desired outcome of the empowerment of women. To be fully empowered, women must participate as equal partners in the development and conduct of their societies. The CDHS 2005 explored women's involvement in civil society in Cambodia by asking women whether they were members of any kind of association, group, or club that holds regular meetings; whether they vote always, sometimes, or never in local or national elections; and about their knowledge of laws in Cambodia protecting

women's rights and about the problem of trafficking in women. Table 20.12 shows the data on women's organization membership and voting behavior by background characteristics. Women's knowledge about laws protecting women's rights and about trafficking in women is shown by background characteristics in Table 20.13.

Table 20.12 Involvement in civil society

Percentage of women who are members of some organization, and percent distribution of women by voting status in national or local elections, according to background characteristics, Cambodia 2005

Background characteristic	Member of some organization	Voting status					Total	Number
		Votes always/sometimes	Never votes	Too young	Never an election	Missing

Few women (6 percent) in Cambodia are members of any association, club, or organization. The types of organizations and groups that women mention being members of include development committees, religious groups, and social groups (data not shown). Women's participation in civil society by exercising their vote is, by contrast, quite significant: overall, 76 percent of women always or sometimes vote. The percentage of women who do not vote is highest among the youngest women largely because some of them are not old enough to vote or to have voted in the last election. The likelihood that women vote also declines with increasing level of education.

Less than half (42 percent) of the women in Cambodia have heard of any laws that protect women's rights, and 66 percent have heard of trafficking in women (Table 20.13). Regarding knowledge of specific laws protecting the rights of women, women most often mentioned the laws against trafficking in women (25 percent) followed by the equal rights law (23 percent) and laws on marriage and divorce (6 percent). Only 3 percent mentioned knowing about labor laws, and 6 percent mentioned knowing about laws on marriage and divorce. Knowledge of one or more laws increases sharply with education from only 31 percent of women with no education knowing any law to 56 percent for women with secondary or higher education. Knowledge also varies greatly by region. Only 9 percent of women in Preah Vihear and Steung Treng know of any law protecting the rights of women, compared with 99 percent of women in Otdar Mean Chey.

In recent years, there has been increasing concern about violence against women in general, and domestic violence in particular, in both developed and developing countries (United Nations General Assembly, 1991). Not only has domestic violence against women been acknowledged worldwide as a violation of the basic human rights of women, but an increasing amount of research highlights the health burdens, intergenerational effects, and demographic consequences of such violence (e.g., Kishor and Johnson, 2006). In many societies, including Cambodia, women are socialized to accept, tolerate, and even rationalize domestic violence and to remain silent about such experiences (Zimmerman, 1994).

Tolerance and experience of domestic violence are significant barriers to the empowerment of women, with consequences for women's health, their health-seeking behavior, their adoption of a small family norm, and the health of their children. With this in mind, Cambodia's Ministry of Women's Affairs began the work of introducing draft domestic violence legislation in 2001; this legislation was adopted by the National Assembly on October 24, 2005. Women's organizations and other non-governmental organizations are still working to educate citizens about the new domestic violence law, which criminalizes acts of domestic violence, provides for the protection of victims, and allows neighbors or local organizations to intervene when domestic violence is occurring.

The CDHS 2005 included a module of questions that provides extensive information on the experience of domestic violence by women in Cambodia at the hands of husbands and others. Specifically, the module provides information on the prevalence of any violence against ever-married women by husbands or other persons (since age 15). For violence by the current or last husband (for women not currently in union), information is sought on the type of violence (emotional, physical, or sexual) and the timing of the initiation of the violence. In addition, the degree of marital control exercised by the husband, violence during pregnancy, and violence by women against their husband are also measured. For women who have experienced any physical or sexual violence, information is collected on whether and from whom help was sought.

There tends to be a culture of silence around the topic of domestic violence that makes the collection of data on this sensitive topic particularly challenging. Even women who want to speak about their experience with domestic violence may find it difficult because of feelings of shame or fear. The need for establishing a rapport with the respondent, ensuring confidentiality, and ensuring privacy during the interview are all important for the entire survey but are critical in ensuring the validity of the data on domestic violence. Complete privacy is also essential for ensuring the security of the respondent and the interviewer. Asking about or reporting violence, especially in households where the perpetrator may be present at the time of interview, carries the risk of further violence. Given all of these concerns related to the collection of data on violence, the CDHS 2005 took the following steps to ensure the validity of the data and the security of respondents and interviewers:

- Training was provided to interviewers to sensitize them to the problem of domestic violence in Cambodia and to the specific challenges involved in collecting data on violence. The need to form a rapport with the respondent and ensure privacy was emphasized both in teaching and practice.
- The module was specially designed to allow the interviewer to continue the interview only if privacy was ensured. If privacy could not be obtained, the interviewer was instructed to skip the module, enter an explanation of what happened, thank the respondent, and end the interview. Notably, in Cambodia, only 34 women selected for interview with the module were not interviewed due to security considerations.

- Only one woman in each household of the one-quarter sub-sample selected for the household relations module was administered the questions. In households with more than one eligible woman, the woman administered the module was selected using a simple method to make a completely random selection. This procedure does not adversely affect the representativeness of the violence data for Cambodia. By interviewing only one woman in each household about domestic violence, any security breach due to other persons in the household knowing that information on domestic violence was given was minimized.
- Informed consent of the respondent was obtained for the survey at the start of the CDHS interview. In addition, at the start of the module, each respondent was read a statement informing her that she was now going to be asked questions that could be personal in nature because they explored different aspects of the relationship between couples. The statement assured her that her answers were completely confidential and would not be told to anyone else and that no one else in the household would be asked these questions.
- Interviewers were provided with a list of organizations that provide services or referrals to victims of domestic violence and were instructed to give a copy of the list to abused women who appealed to them for help.

The domestic violence module was implemented in the same subsample of households as the women's status module, which consisted of one-fourth of the households selected for the 2005 CDHS.

21.1 APPROACH TO VIOLENCE MEASUREMENT

Research on violence suggests that the most common form of domestic violence for adults is spousal violence. Thus, spousal violence was measured using a modified and greatly shortened conflict tactics scale (CTS) used by Strauss (1990). This scale has been found to be effective in measuring domestic violence and can be easily adapted for use in different cultural situations. In the 2005 CDHS, spousal violence was measured using the following set of questions:

Does/Did your (last) husband ever—

- a) Push you, shake you, or throw something at you?
- b) Slap you or twist your arm?
- c) Punch you with his fist or with something that could hurt you?
- d) Kick you or drag you?
- e) Try to strangle you or burn you?
- f) Threaten you with a knife, gun, or other type of weapon?
- g) Attack you with a knife, gun, or other type of weapon?
- h) Physically force you to have sexual intercourse even when you did not want to?
- i) Force you to perform types of other sexual acts you did not want to?

The questions were asked with reference to the current husband for women currently married and the last husband for women not currently married. Women could answer with a “yes” or a “no” to each item, and in cases when the answer was a “yes,” women were asked about the frequency of the act in the 12 months preceding the survey. A “yes” to one or more of items (a) to (d) constitutes evidence of ostensibly less severe physical violence, a “yes” to one or more of items (e) to (g) constitutes evidence of ostensibly more severe physical violence, and a “yes” to items (h) or (i) or both constitutes evidence of sexual violence.

A similar approach was used to measure the prevalence of emotional violence. Respondents were asked the questions:

Does/Did your (last) husband ever—

- a) Say or do something to humiliate you in front of others?
- b) Threaten you or someone close to you with harm?
- c) Swear at you?

This approach of asking separately about specific acts has the advantage of not being affected by different understandings of what constitutes violence. A woman has to say whether she has, for example, ever been “slapped,” not whether she has ever experienced any “violence.” All women would probably agree on what constitutes a slap, but what constitutes a violent act or is understood as violence may vary across women as it does across cultures. Summary terms such as “abuse” or “violence” were not used in the title, design, or implementation of the module. The modified CTS approach also has the advantage of giving the respondent multiple opportunities to disclose any experience of violence.

In addition to spousal violence, the CDHS 2005 asked women whether they had experienced violence at the hands of anyone other than their current or last husband using the question: “From the time you were 15 years old has anyone other than your (current/last) husband hit, slapped, kicked, or done anything else to hurt you physically?” Women who responded yes to this question were asked about the person(s) who had done this and the frequency of such violence during the 12 months preceding the survey. Similar questions were used to measure violence during pregnancy and violence by women against their husband. Finally, new questions on sexual violence have been added to the 2005 CDHS. All women regardless of marital status were asked about whether or not a woman’s first experience of sexual intercourse was forced against her will: “The first time that you had sexual intercourse, would you say that you had it because you wanted to, or because you were forced to have it against your will?” If the respondent answers in the affirmative to this question, she was then asked, “Were you physically forced?”

This review of questions shows that the 2005 CDHS uses a mix of approaches to measure domestic violence. More detail is available for spousal violence than for violence by other persons. The predominance of spousal violence in domestic violence justifies this emphasis on spousal violence.

21.2 WOMEN’S EXPERIENCE OF VIOLENCE SINCE AGE 15 AND RECENT VIOLENCE IN THE 12 MONTHS PRECEDING THE SURVEY

Table 21.1 shows the percentage of ever-married women who have experienced violence since age 15 and in the 12 months preceding the survey by background characteristics. A woman is said to have experienced any violence if she reported violence by a current or previous husband at any time or violence by anyone else since she was age 15. Similarly, recent violence (violence in the 12 months preceding the survey) includes violence by husbands or anyone else.

Table 21.1 Experience of beatings or physical mistreatment

Percentage of ever-married women who have experienced violence since age 15 and percentage who have experienced violence during the 12 months prior to the survey, by background characteristics, Cambodia 2005

Background characteristic	Percentage who have experienced violence:		Number of women
	Since age 15	In the past 12 months	
Age

Education			
No education	29.3	13.4	514
Primary	22.8	10.9	1,193
Secondary and higher	10.0	3.3	330
Employment status			
Employed for cash	23.9	11.6	876
Employed not for cash	21.4	8.9	496
Not currently working	20.8	9.6	660
Total	22.3	10.3	2,037

Note: Total includes 4 women for whom information on employment status is not available.

Just over one-fifth of ever-married women in Cambodia age 15-49 has experienced physical violence since age 15; one out of ten women has experienced violence in the 12 months preceding the survey. This implies that among women who have ever experienced violence, about half have experienced violence in the recent past. Table 21.2 shows that the most common form of violence is violence by current or previous husbands: 65 percent of women reported violence by a husband (alone or with others). Women who are currently divorced or separated were somewhat more likely than women who are either currently married or widowed to report that their husbands were the perpetrators of the violence they experienced.

Table 21.2 Perpetrators of violence

Percent distribution of women who have experienced any physical violence since age 15 by perpetrator of the violence, according to current marital status, Cambodia 2005

Current marital status	Perpetrators					Total	Number of women
	Husband only	Previous husband only	Husband and others	Person other than husband	Cannot establish perpetrator		
In union	52.2	1.6	10.3	32.1	3.8	100.0	381
Divorced/separated	(0.0)	(63.2)	(10.5)	(25.6)	(0.8)	100.0	48
Widowed	(0.0)	(52.5)	(10.2)	(35.3)	(2.0)	100.0	26
Total	43.7	11.0	10.3	31.6	3.4	100.0	455

Note: Figures in parentheses are based on 25-49 unweighted cases.

There is some variation in the reported prevalence of violence by background characteristics (Table 21.1). Prevalence is somewhat higher among women age 30-39 than among younger women and older women. Over a third of currently divorced or separated women reported experiencing violence since age 15; however, divorced or separated women are about equally as likely as women currently in union to report violence in the recent past. The prevalence of any violence is similar in urban and rural areas, while recent reporting of violence is somewhat higher in rural areas. Regarding region, prevalence is highest in Otdar Mean Chey, where 34 percent of ever-married women reported having experienced any violence and 19 percent reported violence in the 12 months preceding the survey. The prevalence of both any violence and recent violence is also relatively high in Prey Veng and Pursat. Prevalence of any violence and violence in the 12 months preceding the survey are both lowest in Kampot/Krong Kep (7 percent and 2 percent, respectively). The prevalence of violence decreases with increasing levels of education. However, even among the most educated women, 10 percent reported having experienced violence, while 3 percent reported experiencing violence in the 12 months preceding the survey.

21.3 VIOLENCE DURING PREGNANCY

Although the experience of violence at any time is likely to have adverse consequences for women's mental and physical health, violence during pregnancy carries additional risks to women's health and survival (due to the added vulnerability from being pregnant) and to the health and survival of the unborn child. Table 21.3 shows that 3 percent of ever-married women have experienced physical violence during pregnancy. Ten percent of widowed women reported violence during pregnancy, compared with 3 percent of currently married women and 6 percent of divorced and separated women. By region, the prevalence of violence during pregnancy varies from 0 percent in Kandal and Kampot/Krong Kep to 6 percent in Banteay Mean Chey. Women who are employed for cash are the most likely to report violence during pregnancy than women of other employment statuses, and women with secondary or higher education are the least likely to report the experience of domestic violence compared with women of other educational levels.

21.4 MARITAL CONTROL

Spousal violence rarely occurs in isolation from other controlling behaviors. Attempts by husbands to control the different aspects of the lives of their wives can be precursors to violent behaviors. To measure the degree of marital control exercised by husbands, ever-married women were asked whether their husband displayed any of the following behaviors: the husband was jealous or angry if she talked to other men, frequently accused her of being unfaithful, did not permit her to meet with her girlfriends, tried to limit her contact with her family, insisted on knowing where she was at

all times, and did not trust her with any money. Table 21.4 shows the percentage of women who said yes to each of the different behaviors and the percentage of women whose husband displayed none of these behaviors. However, the display of a complex of related behaviors is more informative than the display of any single behavior. Thus, Table 21.4 also shows the percentage of women who said that their husband displayed three or more of the listed behaviors.

Table 21.4 Marital control exercised by husband

Percentage of ever-married women whose husband displays various controlling behaviors, by background characteristics, Cambodia 2005

Background characteristic	Percentage of women whose husband:								
	Is jealous if she talks to other men	Accuses her of being unfaithful	Does not permit meetings with girl friends	Tries to limit contact with family	Insists on knowing where she is at all times	Does not trust her with money	Does at least 3 of these behaviors	Does none of these behaviors	Number of women

Total	19.3	11.7	6.5	4.6	6.3	8.1	8.5	75.4	2,037

Note: Table is based on information for the current or most recent husband. Total includes 4 women for whom information on employment status is not available, and 70 women for whom information on interspousal age difference is not available.

The behavior women reported most often was that their husband was jealous if they talked to other men: this behavior was reported by one in five women (19 percent). Nine percent of women reported their husband displayed three or more of these behaviors. Three-quarters of women said that their husband did not display any of these behaviors. While the majority of women have marriages in which the husband imposes a minimal amount of control, about one in ten women are (or were) in marriages in which a substantial degree of marital control is (or was) displayed by the husband.

Women who are currently divorced or separated are most likely to report a high level of marital control in their last marriage (husband displays at least three of the controlling behaviors): 35 percent of these women said that their last husband displayed at least three of the controlling behaviors. Women who have no living children are twice as likely as women with living children to have husbands who display a high level of marital control.

21.5 INTERSPOUSAL VIOLENCE

Violence between spouses can take many forms: emotional, physical, sexual, or a combination of these. Sometimes such violence results in measurable health consequences such as physical injuries that require medical attention. Husbands are not always the perpetrators of spousal violence; sometimes wives initiate spousal violence.

Prevalence of Violence by Husbands

Table 21.5 shows the percentage of women who reported experiencing different types of violence. The types of violence are not mutually exclusive, and some women reported experiencing multiple forms of violence.

Nineteen percent of ever-married women reported experiencing emotional violence by husbands, 13 percent reported physical violence, and 3 percent reported sexual violence. As expected, there is considerable overlap between the types of violence experienced by women: 14 percent reported physical or sexual violence and 22 percent reported physical, sexual, or emotional violence. The 2000 CDHS and the 1996 Household Survey on Domestic Violence in Cambodia (Ministry of Women's Affairs and Project Against Domestic Violence, 1996) found that 16 percent of women surveyed had been physically abused by their partner.

The prevalence of different types of violence generally increases with age. Women who are divorced or separated reported the highest rates of violence: 33 percent experienced emotional violence, 24 percent experienced physical violence, and 6 percent experienced sexual violence at the hands of their last husband. These relatively high rates of marital violence (and also of violence during pregnancy and the high degree of marital control noted in Tables 21.3 and 21.4, respectively) perhaps reflect the reason these women are divorced, as well as a greater willingness to disclose violence among women who are no longer with the abusive husband. Women who are currently married but have been married more than once also report somewhat higher rates of violence than other currently married women who have been married only once.

Interestingly, while women with no living children are the most likely to report that their husbands exhibit a high level of control, they are the least likely to report physical violence. The prevalence of physical or sexual violence is lowest (7 percent) among women with secondary or higher education, compared with women with less education. A higher percentage of women who are employed for cash reported all three forms of violence as compared with women in other employment categories.

Note: Table is based on information for the current or most recent husband. Total includes 4 women for whom information on employment status is not available.

Frequency of Physical or Sexual Violence by Husbands

To determine how many women continue to experience violence at the present time, women were asked for each act ever committed by the husband, the number of times that he committed the act in the 12 months preceding the survey. From Figure 21.1, it is clear that the majority of women who have ever experienced any physical or sexual violence have also experienced it in the 12 months preceding the survey. Among the different physically violent acts, the ones most often reported by women include being slapped or having their arm twisted, and being pushed, shaken, or having something thrown at them. Ten percent of women reported having been slapped or having their arm twisted and 8 percent reported having been pushed, shaken, or had things thrown at them by their husband in the 12 months preceding the survey. The violent act least reported was being attacked with a weapon; 3 percent of women reported ever being forced to have intercourse and less than 1 percent reported ever having been forced to perform other sexual acts.

Figure 21.1 Percentage of Ever-married Women Who Have Experienced Different Forms of Violence from Their Husband Ever and in the Past 12 Months

Note: Figure is based on information for the current or most recent husband.

CDHS 2005

Among women who reported ever experiencing spousal violence (Table 21.6), two-thirds had experienced the violence in the 12 months preceding the survey. Thirty-one percent had experienced spousal violence three or more times in the 12 months preceding the survey. Women with one or two children were more likely than women with more children to have reported frequent spousal violence. Women with secondary or higher education were less likely to have experienced frequent violence than women with less education. Women who were employed for cash were most likely (35 percent) to have experienced frequent violence and women who were employed but did not earn cash were least likely (23 percent) to have experienced frequent violence in the year preceding the survey.

Initiation of Violence by Husband

To study the timing of the initiation of marital violence, women who reported any spousal physical or sexual violence were asked, "How long after you got married to your (last) husband did (this/any of these things) first happen?"

From Table 21.7, it is clear that for most women violence starts early in the marriage. In about two-thirds of marriages, violence first occurred within five years of marriage, and in one-third of marriages it first occurred within two years. The median duration of marriage at which violence first occurred is 3.7 years; that is, for 50 percent of women who have experienced any violence in their marriage, the violence began within the first four years of marriage. One percent of all ever-married women who had experienced spousal violence reported that the violence was initiated before marriage. This is not surprising given that a large minority of women have known their husbands-to-be for a month or less prior to marriage (see Table 15.1).

Table 21.7 Onset of spousal violence

Percent distribution of ever-married women who have experienced physical or sexual violence by their husband by number of years between marriage and first experience of violence, according to marital status and number of marriages, Cambodia 2005

Current marital status	Onset of violence							Total	Median number of years	Number of women

Consequences of Violence

Women were asked the following: “Did the following ever happen because of something your (last) husband did to you: a) you had bruises and aches? b) you had an injury or a broken bone? and c) you went to a health facility as a result of something your husband had done to you?” The three “consequences” asked about cannot be taken to be measures of the severity of violence. Instead a “yes” on each suggests only that the woman experienced adverse health outcomes because of something the husband did. In addition, the interpretation of responses to (c) is likely to be confounded by the fact that not all women who need to access a health facility are in a position to do so. Nonetheless, some insight into the relationship of these “outcomes” to the type/severity of violence can be obtained by tabulating, as in Table 21.8, the “consequences” data by the type of violence reported earlier by women.

Among ever-married women, 6 percent reported ever having had bruises or aches, and 4 percent reported having bruises and aches in the past year because of something their husband did. Bruises and aches are much more common than injuries and broken bones. One percent of all women reported receiving an injury or a broken bone because of something their husband did. One percent of women also reported visiting a health facility because of something their husband did.

Women who experienced severe violence are most likely to suffer consequences. Among women who reported ever experiencing severe physical violence, 50 percent reported ever having bruises and aches, and 37 percent reported having them in the prior 12 months, 14 percent reported having had an injury or a broken bone, and 13 percent reported having had to go to a health facility. For women experiencing less severe violence, the rates of injury are all lower than for women who experienced more severe violence but are nonetheless substantial. For example, 24 percent of women who ever experienced less severe physical violence reported receiving bruises and aches in the prior 12 months. Women who reported sexual violence are likely to have a high incidence of physical outcomes, in part because almost all women who reported sexual violence also reported some other form of physical violence. Similarly, the bruises, aches, injuries, and broken bones reported by women who experienced emotional violence are in part due to the overlap of emotional violence with other types of violence, but may also be due to some women not reporting the acts that resulted in these outcomes within the categories of physical and sexual violence they were provided.

Interspousal Violence by Spousal Characteristics and Women's Status Indicators

Table 21.9 allows a more detailed examination of how women's experience of violence varies with the characteristics of their husband and marriage, by family structure, and by their status within the household.

While women are less likely to have experienced violence when their husband has a secondary or higher education, still 10 percent of such women have experienced physical or sexual violence. Women's experience of violence varies with the extent of alcohol consumption by the husband. Women whose husbands get drunk are over six times more likely to have experienced physical or sexual violence than women whose husbands do not drink or do not get drunk. Overall, 88 percent of women whose husbands do not get drunk have not experienced any violence, compared with 48 percent of women whose husbands get drunk frequently.

Currently married women who are older than or the same age as their husband are most likely to experience emotional, physical, or sexual violence. By spousal education difference, in line with expectations, violence is least common among women who are equally educated as their husband.

Another important characteristic of marriages is the degree of marital control that a husband exercises. It is expected that the higher the degree of marital control, the higher the risk of violence in the marital relationship. Table 21.9 bears this out. Based on the items listed in Table 21.4, the higher the degree of control, the higher the likelihood that the woman has experienced all types of violence. For example, among women in marriages with low marital control (husband does not display any of the listed behaviors), 8 percent each reported ever experiencing physical or sexual violence, whereas among women in marriages with a high level of marital control (husband displays at least three of the six behaviors), 42 percent reported physical or sexual violence. The results for violence in the 12 months preceding the survey by marital control are equally dramatic.

Table 21.9 Spousal violence, women's status, and spousal characteristics

Percent of ever-married women who experienced specific types of violence by their husband ever (since age 15) and in the 12 months prior to the survey, and percentage who have been violent to their husband by selected women's status, spousal, and household characteristics, Cambodia 2005

Total	18.5	13.9	12.8	7.9	2.7	1.7	13.7	8.7	77.7	5.8	3.4	2,037

Note: Table is based on information for the current or most recent husband. Total includes 70 women for whom information on interspousal age difference is not available, and 108 women for whom information on alcohol consumption by husband is not available. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.

¹ For the reasons included, see Table 20.8.

² For the decisions included, see Table 20.4.

³ For the items included, see Table 21.4.

The two empowerment variables (women's agreement with reasons to refuse sex with husband and number of household decisions the respondent participates in) are associated with experience of physical and sexual violence in opposite directions. Women who say that a woman can refuse sex for all given reasons are less likely to report ever-experiencing physical or sexual violence than women who do not agree with all given reasons for a wife to refuse sex to her husband (12 percent as compared with 18 percent, respectively). However, women who participate in three or more household decisions are more likely than women who do not to report having experienced

physical and sexual violence. This, however, may reflect the fact that previously married women are both more likely to report violence from their former spouse as well as more likely to be making their own household decisions. Finally, the risk of all kinds of violence is slightly higher for women living in nuclear families (husband and wife with or without children) than in non-nuclear families (all other combinations of adults and children).

Violence by Wives Against Their Husbands

Women may sometimes be the perpetrators of violence. In most cultures, however, the rate of spousal violence initiated by wives is only a fraction of the rate of spousal violence initiated by husbands. The 1996 Household Survey on Domestic Violence in Cambodia (Ministry of Women's Affairs and Project Against Domestic Violence, 1996) found that 3 percent of men reported being physically abused by their wives. In the CDHS 2005, to measure violence by wives against their husband, women were asked, "Have you ever hit, slapped, kicked, or done anything else to physically hurt your (last) husband at times when he was not already beating or physically hurting you?" Six percent of women reported having ever hit, slapped, kicked, or done something to physically hurt their husband when he was not doing anything to hurt them. Three percent said that they have done so in the 12 months preceding the survey. These rates of violence by women against their husband do not vary between most subgroups of women. There are, however, a few exceptions. The rates of abuse by wives against their husbands were higher for women whose husbands got drunk often (18 percent); they were also higher for women in marriages in which the husband displayed excessive marital control (23 percent).

21.6 EXPERIENCE OF FORCED SEX AT SEXUAL INITIATION

The 2005 CDHS for the first time collected data about use of force during first sexual intercourse. Table 21.10 indicates that among all Cambodian women who report that they have ever had sex, 3 percent experienced their first sexual intercourse by force against their will. The same proportion of women reported a forced first sex regardless of whether their first sexual intercourse occurred at the time of first marriage or before first marriage.

21.7 HELP-SEEKING BEHAVIOR BY WOMEN WHO HAVE EXPERIENCED VIOLENCE

The CDHS 2005 asked all women who had reported any physical or sexual violence by their husbands, or any physical violence by anyone else, if they had ever tried to get help. Table 21.11 shows the percentage of women who sought help by the perpetrator of the violence and by the frequency of violence in the 12 months preceding the survey.

Table 21.10 Experienced force at sexual initiation

Percentage of women age 15-49 who have ever had sexual intercourse who say that their first experience of sexual intercourse was forced against their will, by age at first sexual intercourse and whether the first sexual intercourse was at the time of marriage or before first marriage, Cambodia, 2005

First sexual experience	Percentage whose first sexual intercourse was forced against their will	Number of women who have ever had sex
Age at first sexual intercourse		
< 15	1.9	55
15-19	3.0	999
20-24	2.9	713
25-29	2.4	158
30-49	3.0	51
First sexual intercourse was		
At the time of first marriage/ first cohabitation	2.9	1,841
Before first marriage/ first cohabitation	2.8	134
Total	2.8	2,037

Note: Total includes 62 women for whom information on age at first sexual intercourse is not available.

Overall, nearly one in three women who had experienced violence asked someone for help. This is an increase from the 2000 CDHS, when only one in five women reported seeking help and may reflect the influence of the draft legislation on domestic violence that was pending during the years between CDHS surveys. Women were most likely to seek help from their own family (51 percent) or from some other source (46 percent). Women were least likely to have sought help if the perpetrator of violence was a person other than a husband (23 percent). By contrast, one-third of women who experienced violence by their husband and others (38 percent) or women who experienced violence by a previous husband (53 percent) sought help. Among women who were beaten one or more times in the past year, help seeking increased with the frequency of violence, from 31 percent for women who experienced violence only once in the 12 months preceding the survey to 52 percent for women who experienced violence four or more times in the period. In the 2000 CDHS, only 33 percent of women hit four or more times in the past year sought help to stop the violence.

Table 21.11 Help-seeking behavior among all women who have experienced violence

Among all women who reported having ever experienced any physical or sexual violence, the percentage who tried to get any help, and the distribution of women who sought help according to the type of person from whom they sought help, by perpetrator of the violence and frequency of the violence, Cambodia 2005

Perpetrator/frequency of violence	Percentage who have sought help	Number of women who experienced physical or sexual violence ¹	Persons from whom help was sought				Number of women who sought help ²
			Own family	In-laws	Other relatives/friends	Other	
Persons perpetrating violence							
Husband only	31.4	197	45.9	9.5	17.4	48.5	62
Earlier husband only	(52.6)	50	*	*	*	*	26
Husband and others	37.5	49	(38.6)	(24.6)	(12.2)	(50.9)	18
Others only	22.5	223	51.9	0.0	1.1	49.3	50
Frequency of violence in past year							
None	25.9	303	51.6	6.4	8.1	44.5	78
1 time	30.7	86	*	*	*	*	26
2-3 times	33.0	77	(53.4)	(8.2)	(21.6)	(51.5)	26
4 or more times	52.4	65	(37.4)	(11.8)	(6.0)	(55.5)	34
Total	31.0	538	50.5	7.3	9.6	45.8	167

Note: Figures in parentheses are based on 25-49 unweighted cases. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.

¹ Total includes 19 women for whom information on person perpetrating the violence is not available, and 7 women for whom information on frequency of violence in last year is not available.

² Total includes 10 women for whom information on person perpetrating the violence is not available, and 2 women for whom information on frequency of violence in last year is not available.

A.1 INTRODUCTION

The 2005 Cambodia Demographic and Health Survey (CDHS 2005) is the second national Demographic and Health Survey conducted in Cambodia. The first one was conducted in 2000. CDHS 2005 calls for a nationally representative sample of 18,000 interviews of women between the ages of 15 and 49. The survey is designed to provide information on fertility and childhood mortality, family planning, maternal and child health, knowledge and behavior regarding AIDS and other sexually transmitted infections (STI), domestic violence, and HIV prevalence among the adult population. Survey estimates will be reported for 19 study domains, of which 14 are individual provinces (Banteay Mean Chey, Kampong Cham, Kampong Chhnang, Kampong Speu, Kampong Thom, Kandal, Phnom Penh, Prey Veng, Pursat, Svay Rieng, Takeo, Kratie, Siem Reap and Otdar Mean Chey) and five are groups of provinces. The composition of the five groups of provinces is as follows:

- Group 1: Battambang and Krong Pailin;
- Group 2: Kampot and Krong Kep;
- Group 3: Krong Preah Sihanouk and Kaoh Kong;
- Group 4: Preah Vihear and Steng Treng; and
- Group 5: Mondol Kiri and Rattanak Kiri.

In addition, a men's survey was conducted in a subsample of one out of two (50 percent) households selected for the women's survey. All men ages 15-49 in the selected households were eligible for the men's survey. The survey was designed to collect information on family planning, knowledge and behavior regarding AIDS, and other STIs. All men ages 15-49 and all women ages 15-49 in the selected households for the male survey were also eligible for HIV testing

A.2 SAMPLING FRAME

The sampling frame used for CDHS 2005 is the complete list of all villages in the 1998 Cambodia General Population Census (GPC). In addition, 166 villages not in the GPC 1998 were provided by the National Institute of Statistics (NIS). The sampling frame consists of 13,505 villages throughout the nation. The frame includes information about the villages' locality, number of regular households, population size, type of residence (urban/rural), and other socioeconomic information. A map delimitating village boundaries was also created. Of the 13,505 villages, 1,312 villages are urban and 12,193 villages are rural. The size of the villages (e.g., the number of regular households in the village) varies from 0 to 3,732, with an average of 161 households.

Table A.1 shows the distribution of the villages by province and type of residence. The percent distribution of the population by study domain and type of residence is shown in Table A.2. The distribution shows a great diversity in domain size. In terms of population, the largest domain is the province Kampong Cham, which represents 14.1 percent of the total population. The smallest domain is the province Otdar Mean Chey, which represents only 0.6 percent of the total population. The urban/rural distribution of each study domain is also shown in Table A.2. The urbanization level varies from 2.8 percent (Kampong Cham) to 64.5 percent (the group of Kaoh Kong and Krong Preah Sihanouk). For the nation as a whole, 15.6 percent of the population lives in urban areas.

Code	Province	Number of households		Number of villages		Province total	
		Urban	Rural	Urban	Rural	Household	Village
1	Banteay Mean Chey	18,201	94,655	59	555	112,856	614
2	Battambang	25,248	124,022	62	556	149,270	618

A.3 SAMPLE ALLOCATION

Sample allocation plays an important part in sample design because it relates to the survey precision at the national level. In the absence of accurate information on the main survey indicators at the domain level, the best allocation is proportional allocation. The allocation is proportional to the domain's target population size. Since the desired sample size at the national level is large (18,000 completed women interviews between the ages of 15 and 49), survey precision at the national level is

not the only goal. Rather, given the large number of study domains (19 domains), the survey precision at domain level was a primary concern for the CDHS 2005 design.

To ensure comparability across the study domains, the sample size for each domain should be close. Due to the diversity of domain size, however, proportional allocation could not be used. For example, the smallest province, Otdar Mean Chey, would have had only 108 completed women interviews. The experience from other DHS surveys shows that a sample size of 800 completed women interviews is necessary to provide satisfactory precision. Therefore, an equal size allocation was adopted. This means the 18,000 completed women interviews were equally distributed among the 19 study domains. With this approach, some of the large domains will be undersampled and some of the small domains will be oversampled. Urban and rural areas of Cambodia are two different study domains. Given the small percentage (15.6 percent) of the urban population, oversampling is applied to urban areas to ensure that the survey precision is comparable across urban and rural areas.

The sample allocation between urban and rural areas is a power allocation, which is an allocation between proportional allocation and equal size allocation. A power value is applied to achieve a satisfactory sample size. Table A.3 shows the sample allocation of completed women interviews by study domain and by type of residence. Oversampling or undersampling any particular domain does not pose any problems for representativeness if sampling weights are properly calculated and applied in tabulation. (See section 7 for details on weighting and representativeness.)

The above sample allocation must be converted to a number of primary sampling units and a number of households. It was decided to select 24 households in an urban cluster and 28 households in a rural cluster, based on the following facts obtained from 2000 CDHS: there were 1.46 women age 15-49 per urban household and 1.24 per rural household; the household response rate was 95 percent; the individual response rate was 98 percent. Table A.4 below shows the sample distribution of clusters and households by domain and by type of residence. The total number of clusters is 557, with 137 urban clusters and 420 rural clusters. The total number of households selected is 15,048, with 3,288 urban households and 11,760 rural households. The final distribution of complete women interviews is slightly higher because of rounding the numbers of clusters and households.

Domain of study	Women allocation		
	Urban	Rural	Domain
Banteay Mean Chey	237	710	947
Kampong Cham	73	874	947
Kampong Chhnang	167	780	947

A.4 SAMPLING PROCEDURE AND UPDATING OF THE SAMPLING FRAME

The 2005 CDHS sample is a stratified sample selected in two stages. Stratification is achieved by separating every study domain into urban and rural areas. Areas are defined as urban or rural based on the classification in the 1998 GPC, provided by NIS. Therefore the 19 domains are stratified into 38 sampling strata in total. Samples are selected independently in every stratum, by a two-stage selection. This means that 38 independent samples were selected, one from each sampling stratum. Implicit stratifications were achieved at each of the lower geographical or administrative levels by sorting the sampling frame according to the geographical/administrative order and by using a probability proportional to the size selection in the first stage of sampling. The explicit and implicit stratifications together guarantee a better scattering of the sampled points.

In the first stage of selection, 557 villages were selected with a probability proportional to the village size. The village size is the number of households in the village. After this selection and before the data collection, an updating operation was conducted over all of the 557 selected villages. The updating operation consisted of visits to every selected village. During the visits, records were made of every structure found on the ground; structures were identified by type (residential or not); number of households in each residential structure were identified; location map and a sketch map were drawn showing the boundaries of the village and the location of each structure. This important operation guaranteed the quality of the fieldwork and prevented nonsampling errors.

A household list was set up for each selected village. The resulting lists of households served as the sampling frame for the selection of households in the second stage. Some of the selected villages were big. To minimize the task of household listing, villages with more than 300 households were segmented. A segment corresponds to an enumeration area (EA) that was created for the GPC 1998. Size and boundaries were well-defined and maps were available. Among segmented villages, only one EA was selected from the village with a selection probability proportional to the EA size. Household listing was conducted only in the selected EA. Therefore, a CDHS cluster is either a village or an EA.

In the second stage of selection, a fixed number of 24 households were selected in every urban cluster, and 28 households were selected in every rural cluster. They were selected by an equal probability systematic sampling. The decision on number of households selected per cluster is a tradeoff between fieldwork efficiency and precision. All women ages 15-49 in the selected households were eligible for the interview. The advantages of this two-stage selection procedure are:

1. It is simple to implement and reduces possible nonsampling errors.
2. It is easy to locate the selected households, reducing nonsampling errors and nonresponse.
3. The interviewers interview only the households in the preselected dwellings. No allowance for replacement of dwellings prevents survey bias.

A.5 MALE SUBSAMPLE

In the households selected for the female survey in each cluster, a subsample of one out of two (50 percent) households was also selected for men's survey. All men ages 15-49 in the selected households were eligible for the men's survey. Conduct a men's survey on a subsample was based on the budget reduction and finding acceptable precision for men's indicators. The minimum sample size is larger for women than men because complex indicators (such as total fertility and infant and child mortality rates) require larger sample sizes to achieve sampling errors of reasonable size, and these data come from interviews with women. The men's subsample was selected randomly, and is representative for the study domains and for the country as a whole. Table A.5 shows the sample distribution of selected households and the expected completed men interviews according to study domain and type of residence:

Domain of study	Households selected			Eligible men selected			Men completed		
	Urban	Rural	Total	Urban	Rural	Total	Urban	Rural	Total
Banteay Mean Chey	84	308	392	103	328	431	93	295	388

Siem Reap	84	308	392	103	328	431	93	295	388
Svay Rieng	36	364	400	44	387	431	40	349	389
Takeo	36	364	400	44	387	431	40	349	389
Otdar Mean Chey	132	266	398	162	283	445	146	255	401
Group 1	96	294	390	118	313	430	106	282	388
Group 2	60	336	396	74	358	431	66	322	388
Group 3	216	168	384	265	179	443	238	161	399
Group 4	108	280	388	132	298	430	119	268	387
Group 5	96	308	404	118	328	445	106	295	401
Total	1,644	5,880	7,524	2,015	6,256	8,271	1,815	5,634	7,449

Note: The number of men ages 15-49 per household used in the calculation: urban = 1.29; rural = 1.12; as estimated in CDHS 2000 (the census found urban = 1.43; rural = 1.10). Household response rates were assumed to be the same as for the women's survey (95%), and men's response rate was assumed to be 90% (there was no men's survey in the CDHS 2000).

A.6 SAMPLING PROBABILITIES

Sampling probabilities are important survey parameters which are the bases of the sampling weight calculations. The sampling probabilities will be calculated separately for each sampling stage and for each cluster. We use the following notations:

- P_{1hi} : first-stage sampling probability of the i^{th} cluster in stratum h
 P_{2hi} : second -stage sampling probability within the i^{th} cluster (households)

Let a_h be the number of clusters selected in stratum h , M_{hi} the number of households according to the sampling frame in the i^{th} cluster, and M_h the total number of households in the stratum. The probability of selecting the i^{th} cluster in the CDHS 2005 sample is calculated as follows:

$$\frac{a_h M_{hi}}{\sum M_{hi}}$$

Let b_{hi} be the proportion of households in the selected EA compared with the total number of households in cluster i in stratum h if the cluster is segmented, otherwise $b_{hi} = 1$. Then the probability of selecting cluster i in the sample is:

$$P_{1hi} = \frac{a_h M_{hi}}{\sum M_{hi}} \times b_{hi}$$

Let L_{hi} be the number of households listed in the household listing operation in cluster i in stratum h , let g_{hi} be the number of households selected in the cluster. The second stage's selection probability for each household in the cluster is calculated as follows:

$$P_{2hi} = \frac{g_{hi}}{L_{hi}}$$

The overall selection probability of each household in cluster i of stratum h is therefore the production of the two stages selection probabilities:

$$P_{hi} = P_{1hi} \times P_{2hi}$$

A.7 WEIGHTING AND THE REPRESENTATIVENESS

Proper weighting of the survey data is important to guarantee the representativeness of the survey data, and to prevent bias caused by nonresponse. All analysis based on survey data must properly apply the sampling weights to guarantee the validity of the survey findings, especially for a complex survey. In a complex survey, every individual has a special chance (known as inclusion probability) of being selected in the sample. His/her answers must be properly weighted (basically, by the reciprocal of his or her inclusion probability) to be representative. For example, if a particular individual was selected in the sample with a probability of 0.001, then he/she represents 1,000 similar individuals in the base population. Therefore, his/her answers to all of the questions must be multiplied by 1,000 to be representative. If another particular individual is selected with a probability of 0.002, then he/she represents 500 similar individuals in the base population, and therefore will receive a weight of 500. Representativeness means being able to expand the sample to the base population. Since the samples are selected independently in each study domain, they are representative for their corresponding domains, if properly weighted. If each individual sample is representative for its domain, then the overall sample for the country as a whole is representative for the country. Therefore the CDHS 2005 sample is representative for the 19 study domains (14 individual provinces and 5 groups of provinces), for urban and rural areas, and for the country as a whole.

CDHS 2005 is a complex survey including multi-stage, clustering, stratification and unequal probability sampling. The design is essentially a self-weighting design. Because of the non-proportional allocation of the samples to the different 19 reporting domains and their urban rural areas, and the differences in the number of households in the base file and the number of households listed in the household listing operation for each cluster, the self-weighting conditions were no longer met. Therefore weights are required to ensure the actual representativeness of the sample at both domain level and national level.

Several sets of weight are calculated for CDHS 2005 in order to satisfy different users of the dataset. First, a set of household weight was calculated for the selected households. All household indicators were tabulated by applying this set of weight. The sampling weight for each household in cluster i of stratum h is the inverse of its selection probability (calculated in section VI) :

$$W_{hi} = 1 / P_{hi}$$

This weight was further adjusted for non-response at household level. Nonresponse adjustment was essential to prevent bias caused by non-response. For the convenience of statement, the following notations were used:

n_{HH} : the total number of household allocated to the given stratum

n_{HHF} : the total number of households found in the given stratum, $0 \leq n_{HHF} \leq n_{HH}$

n_{HHC} : the total number of households completed the survey in the given stratum,
 $0 \leq n_{HHC} \leq n_{HHF}$

Then the probability of response in the household level in the given stratum is:

$$P_{HH} = \frac{n_{HHF}}{n_{HH}} \times \frac{n_{HHC}}{n_{HHF}} = \frac{n_{HHC}}{n_{HH}}$$

The adjusted weight for each household in cluster i of stratum h is given by:

$$W_{hi}^* = W_{hi} / P_{HHhi}$$

This adjustment was based on the assumption of homogeneity of the response behavior within sampling stratum. This means it was unlikely that one particular household responded to the survey significantly differently from others in the same stratum. This assumption is reasonable because the stratification is based on urban and rural residence, and almost all DHS surveys show differences in response behaviors by urban and rural residence.

The above adjusted weight was further normalized (called standard weight) at the national level to make the number of weighted cases equal to the number of unweighted cases for all household indicators based on the whole national sample. This treatment had no effect on the indicators themselves. But it did affect the number of weighted cases to reflect the relative scale of the base population it represents. The normalization was done by multiplying the whole set of weights by a *unique constant*, which was the number of unweighted total number of households interviewed over the weighted total number of households interviewed:

$$W_{hi}^{**} = W_{hi}^* \times \frac{\sum \sum n_{HHChi}}{\sum \sum (W_{hi}^* \times n_{HHChi})}$$

Second, a set of women individual standard weight was calculated based on the household standard weight calculated above: correct for women nonresponse normalization. Since all women ages 15-49 were interviewed in every selected household, women should share the same weight as that of the household where they belong. And since there are non-responses at individual level, that is, not all of the eligible women in the selected household answered the survey; the household standard weight must be corrected for women's nonresponse. The following notations were used:

n_{WF} : the total number of eligible women found in all of the interviewed households in a given stratum

n_{WC} : the total number of women completed the survey in the given stratum

Then the women's individual weight was calculated by :

$$W_{whi} = W_{hi}^{**} \times \frac{n_{WF}}{n_{WC}}$$

Women's standard weight was calculated by :

$$W_{whi}^* = W_{whi} \times \frac{\sum \sum n_{WChi}}{\sum \sum (W_{whi} \times n_{WChi})}$$

The reason for normalization of the individual weight is the same as for the normalization of household weight. The household standard weight and men's individual standard weight for the male subsample were calculated the same way. The household, women's, and men's weights were cluster weights. All the households in the same cluster shared the same household weights; all women and men in the same cluster shared the same weight for women and men, respectively.

A special set of weight for the domestic violence module was also calculated and normalized the same way. It also adjusted for the selection of only one eligible woman in each household for the domestic violence module. Therefore, the weight for the domestic violence module was an individual weight which was related to the number of eligible women in the household.

A spreadsheet for the calculation of the standard weights was prepared for facilitating the calculation. See "Standard weight calculation for CDHS 2005."

A.8 HIV TESTING AND THE HIV WEIGHTS

CDHS 2005 included HIV testing in a subsample of one out of two (50 percent) households selected for both men's and women's survey. All men ages 15-49 and all women ages 15-49 in the selected households in this subsample were eligible for the HIV testing. Conducting the HIV testing in a subsample was based on the considerations of budget restriction and precision requirement. The CDHS 2005 sample has a size of 18,000 completed women interviews. To get the HIV prevalence level among adult population and for comparison between male and female population. Approximately the same number of male individuals needed to be tested. Therefore, to test all the interviewed women and the same number of men meant a considerable amount of money and a large scale of laboratory work. But for precision considerations, not a large sample was required. Therefore, the best way was to do the HIV testing in the men's subsample.

The individuals tested for HIV were given a special weight for calculating the HIV prevalence. This was different from their survey standard weight for several reasons: First, the response behavior toward HIV testing was different from the response behavior in the main survey. Also, men and women responded differently. Therefore, the HIV weight was calculated by correcting the nonresponse for the individual survey and for HIV testing. Second, the HIV testing was conducted on a subsample. The standardized individual weight includes nontested individuals. Finally, the HIV standard weight was standardized for men and women interviewed together so that the weight was unbiased (or representative) for women and men separately, as well as women and men together. If the men and women's weights are normalized separately, then the HIV prevalence level among the adult population would be biased. The following procedure shows the calculation of the HIV standard weight:

${}_{HIV}n_{WF}$: In the men's subsample, the total number of eligible women found in all of the interviewed households in a given stratum,

${}_{HIV}n_{WC}$: In the men's subsample, the total number of women completed the individual interview and the HIV testing and having a valid test results (due to the special procedure of HIV testing, not all tested individuals has a valid test results) in all of the interviewed households in a given stratum,

${}_{HIV}n_{MF}$: In the men's subsample, the total number of eligible men found in all of the interviewed households in a given stratum,

${}_{HIV}n_{MC}$: In the men's subsample, the total number of men who completed the individual interview and the HIV testing and having a valid test results (due to the special procedure of HIV testing, not all tested individuals has a valid test results) in all of the interviewed households in a given stratum,

W_{hi}^{**} : The household standard weight for the male subsample.

Then the women's individual weight for HIV testing is calculated by :

$${}_{HIV}W_{whi} = W_{hi}^{**} \times \frac{{}_{HIV}n_{WF}}{{}_{HIV}n_{WC}}$$

Then the men's individual weight for HIV testing was calculated by :

$${}_{HIV}W_{mhi} = W_{hi}^{**} \times \frac{{}_{HIV}n_{MF}}{{}_{HIV}n_{MC}}$$

Women's standard weight for HIV testing was calculated by :

$${}_{HIV}W_{whi}^* = {}_{HIV}W_{whi} \times \frac{\sum \sum ({}_{HIV}n_{wChi} + {}_{HIV}n_{mChi})}{\sum \sum ({}_{HIV}W_{whi} \times {}_{HIV}n_{wChi} + {}_{HIV}W_{mhi} \times {}_{HIV}n_{mChi})}$$

Men's standard weight for HIV testing was calculated by :

$${}_{HIV}W_{mhi}^* = {}_{HIV}W_{mhi} \times \frac{\sum \sum ({}_{HIV}n_{wChi} + {}_{HIV}n_{mChi})}{\sum \sum ({}_{HIV}W_{whi} \times {}_{HIV}n_{wChi} + {}_{HIV}W_{mhi} \times {}_{HIV}n_{mChi})}$$

A.9 SPECIAL CONCERNS

As with all the DHS surveys, the target population for the women's survey consists of all women ages 15-49 living in ordinary households who slept in the household the night before the survey (this group is known as the de facto population). The target population for the male survey consists of all men ages 15-49 living in ordinary households who slept in the household the night before the survey. This special definition of target population aims to adapt to the special features of the DHS survey. The data collection procedure lasts for three to six months without a fixed survey date. The de facto population is the most accessible population. The sampling unit is the structure which is identified as ordinary residence structure during the household listing operation, not the

specific household with the special household members living in the structure at the moment of household listing. With the structure as sampling unit, it does not matter whether the actual residents in a selected structure at the moment of the survey are the same as those who lived there at the time of household listing. This prevents sample loss caused by migration. It has other important advantages: the sampled households are located in a fixed place; it is possible to draw a geographical map showing the exact locations of the selected households (by using the maps produced in household listing); and these features assist teams in locating the selected households during data collection. As a result, it is easier to control the field work and to check the exactness of survey implementation. All these features can greatly reduce the nonsampling errors and possible bias, thus contributing to survey precision.

The methodology of the CDHS 2005 makes it possible to capture the migrant population. For the CDHS 2000, a village chief provided a list of households. The list may have included household heads who had migrated to other towns for work. The list also may not have included household heads who had recently migrated into the village. If a selected household had moved away, the sample size was reduced. In circumstances of the migrant population staying in ordinary households (structures used as residential households), migrants will be properly represented in the CDHS 2005 because the sample is drawn from a list of residential structures as the sampling unit, and the de facto population as the target population. De facto refers to those who slept in the selected household the night before the day of interview. Since there is no reason to believe that people who came to the selected household temporarily (non-usual members who slept in the household the night before the interview and are therefore de facto) are different from people who left the selected household temporarily to go somewhere else (usual members who did not sleep in the household the night before the interview and are therefore non de facto), it is safe to assume that the de facto population does not differ from the actual population. Thus, CDHS 2005 survey results are representative of the actual population, including the migrant population.

Refused (EWR)		0.6	0.0	0.3	0.1	0.1	0.4	0.6	0.3	0.1	0.4	
Partly completed (EWPC)		0.0	0.1	0.0	0.1	0.0	0.1	0.4	0.2	0.1	0.1	
Incapacitated (EWI)		0.4	0.7	1.1	0.3	0.8	1.1	0.4	0.3	0.3	0.6	
Other (EWO)		0.3	0.0	0.0	0.0	0.2	0.0	0.0	0.0	0.0	0.1	
Total		100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0	
Number of women		992	843	904	970	1,066	907	829	887	892	17,256	
Eligible women response rate (EWRR)		98.1	98.2	98.2	97.7	97.2	96.3	97.5	98.4	97.0	97.5	
Overall response rate (ORR)		97.7	97.5	97.7	95.3	94.1	93.9	91.4	97.4	94.6	95.5	

¹ Using the number of households falling into specific response categories, the household response rate (HRR) is calculated as:

$$\frac{100 * C}{C + HP + P + R + DNF}$$

² Using the number of eligible women falling into specific response categories, the eligible woman response rate (EWRR) is calculated as:

$$\frac{100 * EWC}{EWC + EWNH + EWP + EWR + EWPC + EWI + EWO}$$

³ The overall response rate (ORR) is calculated as: $ORR = HRR * EWRR/100$

The estimates from a sample survey are affected by two types of errors: (1) nonsampling errors, and (2) sampling errors. Nonsampling errors are the results of mistakes made in implementing data collection and data processing, such as failure to locate and interview the correct household, misunderstanding of the questions on the part of either the interviewer or the respondent, and data entry errors. Although numerous efforts were made during the implementation of the 2005 Cambodia Demographic and Health Survey (CDHS) to minimize this type of error, nonsampling errors are impossible to avoid and difficult to evaluate statistically.

Sampling errors, on the other hand, can be evaluated statistically. The sample of respondents selected in the 2005 CDHS is only one of many samples that could have been selected from the same population, using the same design and expected size. Each of these samples would yield results that differ somewhat from the results of the actual sample selected. Sampling errors are a measure of the variability between all possible samples. Although the degree of variability is not known exactly, it can be estimated from the survey results.

A sampling error is usually measured in terms of the *standard error* for a particular statistic (mean, percentage, etc.), which is the square root of the variance. The standard error can be used to calculate confidence intervals within which the true value for the population can reasonably be assumed to fall. For example, for any given statistic calculated from a sample survey, the value of that statistic will fall within a range of plus or minus two times the standard error of that statistic in 95 percent of all possible samples of identical size and design.

If the sample of respondents had been selected as a simple random sample, it would have been possible to use straightforward formulas for calculating sampling errors. However, the 2005 CDHS sample is the result of a multi-stage stratified design, and, consequently, it was necessary to use more complex formulae. The computer software used to calculate sampling errors for the 2005 CDHS is a Macro SAS procedure. This procedure used the Taylor linearization method for variance estimation for survey estimates that are means or proportions. The Jackknife repeated replication method is used for variance estimation of more complex statistics such as fertility and mortality rates.

The Taylor linearization method treats any percentage or average as a ratio estimate, $r = y/x$, where y represents the total sample value for variable y , and x represents the total number of cases in the group or subgroup under consideration. The variance of r is computed using the formula given below, with the standard error being the square root of the variance:

$$SE^2(r) = var(r) = \frac{1-f}{x^2} \sum_{h=1}^H \left[\frac{m_h}{m_h - 1} \left(\sum_{i=1}^{m_h} z_{hi}^2 - \frac{z_h^2}{m_h} \right) \right]$$

in which

$$z_{hi} = y_{hi} - rx_{hi}, \text{ and } z_h = y_h - rx_h$$

where h represents the stratum which varies from 1 to H ,
 m_h is the total number of clusters selected in the h^{th} stratum,
 y_{hi} is the sum of the weighted values of variable y in the i^{th} cluster in the h^{th} stratum,
 x_{hi} is the sum of the weighted number of cases in the i^{th} cluster in the h^{th} stratum, and
 f is the overall sampling fraction, which is so small that it is ignored.

The Jackknife repeated replication method derives estimates of complex rates from each of several replications of the parent sample, and calculates standard errors for these estimates using simple formulae. Each replication considers *all but one* clusters in the calculation of the estimates. Pseudo-independent replications are thus created. In the 2005 CDHS, there were 557 non-empty clusters. Hence, 557 replications were created. The variance of a rate r is calculated as follows:

$$SE^2(r) = var(r) = \frac{1}{k(k-1)} \sum_{i=1}^k (r_i - r)^2$$

in which

$$r_i = kr - (k-1)r_{(i)}$$

where r is the estimate computed from the full sample of 557 clusters,
 $r_{(i)}$ is the estimate computed from the reduced sample of 556 clusters (i^{th} cluster excluded), and
 k is the total number of clusters.

In addition to the standard error, ISSA computes the design effect (DEFT) for each estimate, which is defined as the ratio between the standard error using the given sample design and the standard error that would result if a simple random sample had been used. A DEFT value of 1.0 indicates that the sample design is as efficient as a simple random sample, while a value greater than 1.0 indicates the increase in the sampling error due to the use of a more complex and less statistically efficient design. ISSA also computes the relative error and confidence limits for the estimates.

Sampling errors for the 2005 CDHS are calculated for selected variables considered to be of primary interest for woman's survey and for man's surveys, respectively. The results are presented in this appendix for the country as a whole, for urban and rural areas, and for each of the 19 study domains. For each variable, the type of statistic (mean, proportion, or rate) and the base population are given in Table B.1. Tables B.2 to B.21 present the value of the statistic (R), its standard error (SE), the number of unweighted (N-UNWE) and weighted (N-WEIG) cases, the design effect (DEFT), the relative standard error (SE/R), and the 95 percent confidence limits ($R \pm 2SE$), for each variable. The DEFT is considered undefined when the standard error considering simple random sample is zero (when the estimate is close to 0 or 1). In the case of the total fertility rate, the number of unweighted cases is not relevant, as there is no known unweighted value for woman-years of exposure to child-bearing.

The confidence interval (e.g., as calculated for *children ever born to women over age 40*) can be interpreted as follows: the overall average from the national sample is 4.927 and its standard error is 0.064. Therefore, to obtain the 95 percent confidence limits, one adds and subtracts twice the standard error to the sample estimate, i.e., $4.927 \pm 2 \times 0.065$. There is a high probability (95 percent) that the *true* average number of children ever born to all women over age 40 is between 4.799 and 5.054.

Sampling errors are analyzed for the national woman sample and for two separate groups of estimates: (1) means and proportions, and (2) complex demographic rates. The relative standard errors (SE/R) for the means and proportions range between 0.1 percent and 16.1 percent with an average of 3.1 percent; the highest relative standard errors are for estimates of very low values (e.g., *currently using condoms*). If estimates of very low values (less than 10 percent) were removed, then the average drops to 2.4 percent. So in general, the relative standard error for most estimates for the country as a whole is small, except for estimates of very small proportions. The relative standard error for the total fertility rate is small, 2.3 percent. However, for the mortality rates, the average relative standard error is much higher, 7.4 percent.

There are differentials in the relative standard error for the estimates of sub-populations. For example, for the variable *want no more children*, the relative standard errors as a percent of the estimated mean for the whole country, and for the urban areas are 1.2 percent and 2.5 percent, respectively.

For the total sample, the value of the design effect (DEFT), averaged over all variables, is 1.39 which means that, due to multi-stage clustering of the sample, the average standard error is increased by a factor of 1.39 over that in an equivalent simple random sample.

Table B.1 List of selected variables for sampling errors, Cambodia 2005

Variable	Estimate	Base population
WOMEN		
Urban residence	Proportion	All women 15-49
No schooling	Proportion	All women 15-49
Secondary and higher education	Proportion	All women 15-49
Never married (never in union)	Proportion	All women 15-49
Currently married (in union)	Proportion	All women 15-49
Married before age 20	Proportion	Women 25-49
Had first sexual intercourse before age 18	Proportion	Women 25-49
Children ever born	Mean	All women 15-49
Children ever born to women over age 40	Mean	Women age 40-49
Children surviving	Mean	All women 15-49
Knowing any contraceptive method	Proportion	Currently married women 15-49
Knowing any modern contraceptive method	Proportion	Currently married women 15-49
Ever used any contraceptive method	Proportion	Currently married women 15-49
Currently using any method	Proportion	Currently married women 15-49
Currently using a modern method	Proportion	Currently married women 15-49
Currently using daily pill	Proportion	Currently married women 15-49
Currently using condom	Proportion	Currently married women 15-49
Want no more children	Proportion	Currently married women 15-49
Want to delay at least 2 years	Proportion	Currently married women 15-49
Mothers received medical care at birth	Proportion	Births in past 5 years
Had diarrhea in past 2 weeks	Proportion	Children under 5
Treated with ORS packets	Proportion	Children under 5 with diarrhea in past 2 weeks
Consulted medical personnel for diarrhea	Proportion	Children under 5 with diarrhea in past 2 weeks
Having health card, seen	Proportion	Children 12-23 months
Received BCG vaccination	Proportion	Children 12-23 months
Received DPT vaccination (3 doses)	Proportion	Children 12-23 months
Received polio vaccination (3 doses)	Proportion	Children 12-23 months
Received measles vaccination	Proportion	Children 12-23 months
Fully immunized	Proportion	Children 12-23 months
Weight-for-height (<-2 SD)	Proportion	Children under 5 who were measured
Height-for-age (<-2 SD)	Proportion	Children under 5 who were measured
Weight-for-age (<-2 SD)	Proportion	Children under 5 who were measured
Total fertility rate (past 3 years)	Rate	Woman-years of exposure to childbearing
Neonatal mortality rate ¹	Rate	Number of births
Postneonatal mortality rate ¹	Rate	Number of births
Infant mortality rate ¹	Rate	Number of births
Child mortality rate ¹	Rate	Number of births
Under-five mortality rate ¹	Rate	Number of births
Experienced violence in past 12 months	Proportion	Ever-married women age 15-49
Maternal mortality rate ² (past 0-6 years)	Rate	Woman-years of exposure
HIV prevalence	Proportion	All women 15-49 who were tested
MEN		
Urban residence	Proportion	All men 15-49
No schooling	Proportion	All men 15-49
Secondary and higher education	Proportion	All men 15-49
Never married (never in union)	Proportion	All men 15-49
Currently married (in union)	Proportion	All men 15-49
Married before age 20	Proportion	All men 25-49
Had first sexual intercourse before age 18	Proportion	All men 25-49
HIV prevalence	Proportion	All men 15-49 who were tested

¹ The mortality rates are calculated for past 5 years for the total sample, and 10 years for the urban, rural and the regional samples.

² The maternal mortality rate is calculated just for the total sample since the regional sample sizes are not big enough for a precise estimation.

* CODES FOR Q. 3 RELATIONSHIP TO HEAD OF HOUSEHOLD:
01 = HEAD
02 = WIFE OR HUSBAND
03 = SON OR DAUGHTER
04 = SON-IN-LAW OR DAUGHTER-IN-LAW
05 = GRANDCHILD
06 = PARENT
07 = PARENT-IN-LAW
08 = BROTHER OR SISTER
09 = NIECE/NEPHEW BY BLOOD
10 = NIECE/NEPHEW BY MARRIAGE
11 = OTHER RELATIVE
12 = ADOPTED/FOSTER/STEPCHILD
13 = NOT RELATED
98 = DON'T KNOW

** CODES FOR Q. 8 MARITAL STATUS:
1 = MARRIED/LIVING TOGETHER
2 = DIVORCED/SEPARATED
3 = WIDOWED
4 = NEVER MARRIED/ NEVER LIVED WITH A PARTNER

To make sure that I have a complete household listing

1) Are there any small children or infants we have not listed? YES LIST NO

2) Any friends, domestic servants, or lodgers who are not members of your family but usually live here? YES LIST NO

3) Did any guests or visitors sleep here last night who have not been listed? YES LIST NO

LINE NO.	SICK PERSON	BASIC MATERIAL NEEDS			SURVIVORSHIP AND RESIDENCE OF BIOLOGICAL PARENTS						
		IF AGE 15 YRS OR OLDER	IF AGE 5-17 YEARS			IF AGE 0-17 YEARS					
	Has (NAME) been very sick for at least three months during the past 12 months? By very sick I mean that (NAME) was too sick to work or do normal activities around the house for at least 3 of the past 12 months.	Does (NAME) have a blanket?	Does (NAME) have a pair of shoes?	Does (NAME) have at least two sets of clothing?	Is (NAME)'s natural mother alive?	Does (NAME)'s natural mother live in this household? IF YES: What is her name? RECORD MOTHER'S LINE NUMBER ...	IF MOTHER DOES NOT LIVE IN HOUSEHOLD Has (NAME)'s mother been very sick for at least 3 months during the past 12 months? By very sick I mean too sick to work or do normal activities around the house for at least 3 of the past 12 months?	Is (NAME)'s natural father alive?	Does (NAME)'s natural father live in this household? IF YES: What is his name? RECORD FATHER'S LINE NUMBER ...	IF FATHER DOES NOT LIVE IN HOUSEHOLD Has (NAME)'s father been very sick for at least 3 months during the past 12 months? By very sick I mean too sick to work or do normal activities around the house for at least 3 of the past 12 months?	CHECK Q.16 AND Q.19: IF YES TO Q.16 AND Q.19 (BOTH PARENTS ALIVE), CIRCLE '1', OTHERWISE CIRCLE '2'.

**RANDOM NUMBER TABLE FOR
SELECTION OF WOMAN AS RESPONDENT TO HOUSEHOLD RELATIONS MODULE**

CHECK THE LAST DIGIT OF THE HOUSEHOLD NUMBER ON THE COVER PAGE OF THE HOUSEHOLD QUESTIONNAIRE.
THIS IS THE NUMBER OF THE ROW TO SELECT.

CHECK THE TOTAL NUMBER OF ELIGIBLE WOMEN IN COLUMN 9 OF THE HOUSEHOLD SCHEDULE.
THIS IS THE NUMBER OF THE COLUMN TO SELECT.

FIND THE BOX WHERE THE ROW AND THE COLUMN MEET AND CIRCLE THAT NUMBER.

THIS IS THE POSITION NUMBER OF THE WOMAN WHO WILL BE ASKED THE HOUSEHOLD RELATIONS MODULE.
IN COLUMN 9 OF THE HOUSEHOLD SCHEDULE,

DRAW A BOX AROUND THE LINE NUMBER OF THE ELIGIBLE WOMAN IN THAT POSITION.

FOR EXAMPLE, IF THE LAST DIGIT OF THE HOUSEHOLD NUMBER IS 6

AND THERE ARE 3 ELIGIBLE WOMEN, THE NUMBER IN THE BOX WHERE ROW 6 AND COLUMN 3 MEET IS 2.

NOW SUPPOSE THE THREE ELIGIBLE WOMEN'S LINE NUMBERS ARE '02', '03', AND '07',

THEN THE WOMAN WITH LINE NUMBER '03' IS SELECTED FOR THE HOUSEHOLD RELATIONS MODULE.

LAST DIGIT HH No.	Total number of eligible women in the household

*** VOLUNTARY CONSENT STATEMENT FOR ANEMIA TESTING**

Hello, my name is _____. I'm from the Ministry of Health and Ministry of Planning.

As part of this survey, we are studying anemia among women and children. Anemia is a serious health problem that results from poor nutrition. This survey will assist the government to develop programs to prevent and treat anemia.

We request that you (and all children born in 2000 or later) participate in the anemia testing part of this survey and give a few drops of blood from a finger. The test uses disposable sterile instruments that are clean and completely safe. The blood will be analyzed with new equipment and the results of the test will be given to you right after the blood is taken. The results will be kept confidential.

If you decide not to have the test done, it is your decision and we will respect your decision.

Please tell me if you agree for yourself (and NAME OF CHILDREN) to participate in the anemia test.

GO TO COLUMN (160). CIRCLE THE APPROPRIATE CODE AND SIGN.

*** VOLUNTARY CONSENT STATEMENT FOR HIV TESTING OF ADULTS AGE 18 OR OLDER**

Hello, my name is _____. I'm from the Ministry of Health and Ministry of Planning.

As part of this survey, we are studying HIV/AIDS among women and men age 15 to 49 years.

As you may know, HIV is the virus that causes AIDS, and AIDS is a serious illness that often leads to death.

We are conducting tests to measure the extent of the disease in Cambodia. The results of the survey will assist the government in developing programs for preventing HIV and AIDS.

We request that you participate in the HIV testing part of this survey by permitting us to take a few drops of blood from your finger. Only disposable, sterile instruments that are clean and completely safe will be used.

The blood sample will be sent to a laboratory to be analyzed. To ensure confidentiality, your name will not be attached to the blood sample.

The results will be completely anonymous and for this reason we cannot provide you with results of the test.

However, if you would like to know your HIV status then we will give you a coupon for a free test at a Voluntary Counseling and Testing center.

I hope you will agree to participate in the testing. But if you decide not to have the test done, it is your right and I will respect your decision.

Do you have any questions about this?

Please tell me if you agree to participate in the HIV test.

GO TO COLUMN (172). CIRCLE THE APPROPRIATE CODE AND SIGN.

THE RESPONDENT HAS THE RIGHT TO REFUSE THE HIV TEST, AND THEREFORE SHOULD NOT BE FORCED.

*** VOLUNTARY CONSENT STATEMENT FOR HIV TESTING OF YOUNG WOMEN AND MEN AGE 15-17 YEARS**

STEP ONE: ASK CONSENT OF THE PARENT OR RESPONSIBLE ADULT.

The study of HIV/AIDS includes young women and men starting at age 15. For testing of young women and men age 15-17 we ask that the parent or responsible adult provide their consent, as well as the eligible young woman or young man.

We request that (NAME) participate in the HIV testing part of the survey by permitting us to take a few drops of blood from her or his finger. Only disposable, sterile instruments that are clean and completely safe will be used.

The blood sample will be sent to a laboratory to be analyzed. To ensure confidentiality, no name or personally identifying information

will be attached to the blood sample. The results will be completely anonymous and for this reason we cannot provide results of the test.

However, if (NAME) wishes to know their status then we will give (NAME) a coupon for a free test at a Voluntary Counseling and Testing center.

Please tell me if you agree for (NAME) to participate in the HIV test.

GO TO COLUMN (171). CIRCLE THE APPROPRIATE CODE AND SIGN.

**STEP TWO: ASK CONSENT OF THE YOUNG WOMAN OR YOUNG MAN.
IF THE PARENT OR RESPONSIBLE ADULT AGREES THAT THE YOUNG PERSON CAN BE TESTED,
READ THE STATEMENT TO THE YOUNG PERSON.**

As part of this survey, we are studying HIV/AIDS among women and men age 15 to 49 years.
As you may know, HIV is the virus that causes AIDS, and AIDS is a serious illness that often leads to death.
We are conducting tests to measure the extent of the disease in Cambodia. The results of the survey will assist the government in developing programs for preventing HIV and AIDS.

We request that you participate in the HIV testing part of this survey by permitting us to take a few drops of blood from your finger. Only disposable, sterile instruments that are clean and completely safe will be used.

The blood sample will be sent to a laboratory to be analyzed. To ensure confidentiality, your name will not be attached to the blood sample. SECTION 1. RESPONDENT'S BACKGROUND

INTRODUCTION AND CONSENT

<p>INFORMED CONSENT</p> <p>Hello. My name is _____ and I am working with the Ministry of Health and Ministry of Planning. We are conducting a national survey about the health of women and children. We would very much appreciate your participation in this survey. I would like to ask you about your health (and the health of your children). This information will help the government to plan health services. The survey usually takes about 45 minutes to complete. Whatever information you provide will be kept strictly confidential and will not be shown to other persons.</p> <p>Participation in this survey is voluntary and you can choose not to answer any individual question or all of the questions. However, we hope that you will participate in this survey since your views are important.</p> <p>At this time, do you want to ask me anything about the survey? May I begin the interview now?</p> <p>Signature of interviewer: _____ Date: _____</p> <p>RESPONDENT AGREES TO BE INTERVIEWED 1 RESPONDENT DOES NOT AGREE TO BE INTERVIEWED ... 2 → END</p>

SECTION 1 - RESPONDENT'S BACKGROUND

INTRODUCTION AND CONSENT

INFORMED CONSENT

Hello. My name is _____ and I am working with the Ministry of Health and Ministry of Planning. We are conducting a national health survey. We would very much appreciate your participation in this survey. I would like to ask you about some important health issues. This information will help the government to plan health services. The survey usually takes around 20 minutes to complete.

Whatever information you provide will be kept strictly confidential and will not be shown to other persons.

Participation in this survey is voluntary and you can choose not to answer any individual question or all of the questions. However, we hope that you will participate in this survey since your views are important.

At this time, do you want to ask me anything about the survey?
May I begin the interview now?

Signature of interviewer: _____ Date: _____
