INTRODUCTION

The 2015-16 National Family Health Survey (NFHS-4), the fourth in the NFHS series, provides information on population, health, and nutrition for India and each state and union territory. For the first time, NFHS-4 provides district-level estimates for many important indicators. All four NFHS surveys have been conducted under the stewardship of the Ministry of Health and Family Welfare (MoHFW), Government of India. MoHFW designated the International Institute for Population Sciences (IIPS), Mumbai, as the nodal agency for the surveys. Funding for NFHS-4 was provided by the United States Agency for International Development (USAID), the United Kingdom Department for International Development (DFID), the Bill and Melinda Gates Foundation (BMGF), UNICEF, UNFPA, the MacArthur Foundation, and the Government of India. Technical assistance for NFHS-4 was provided by ICF, Maryland, USA. Assistance for the HIV component of the survey was provided by the National AIDS Control Organization (NACO) and the National AIDS Research Institute (NARI), Pune.

Four survey questionnaires – household, woman's, man's, and biomarker – were used to collect information in 19 languages using Computer Assisted Personal Interviewing (CAPI). All women age 15-49 and men age 15-54 in the selected sample households were eligible for interviewing. In the household questionnaire, basic information was collected on all usual members of the household and visitors who stayed in the household the previous night, as well as socioeconomic characteristics of the household, water and sanitation, health insurance, and number of deaths in the household in the three years preceding the survey. Two versions of the woman's questionnaire were used in NFHS-4. The first version (district module), which collected information on women's characteristics, marriage, fertility, contraception, reproductive health, children's immunizations, and treatment of childhood illnesses, was fielded in the entire sample of NFHS-4 households. Information on these topics is available at the district, state, and national levels. In the second version of the questionnaire (state module), four additional topics, namely, sexual behaviour, HIV/AIDS, husband's background and women's work, and domestic violence, were also included. This version was fielded in a subsample of NFHS-4 households designed to provide information only at the state and national levels. The man's questionnaire covered the man's characteristics, marriage, number of children, contraception, fertility preferences, nutrition, sexual behaviour, attitudes towards gender roles, HIV/AIDS, and lifestyle. The biomarker questionnaire covered measurements of height, weight, and haemoglobin levels for children; height, weight, haemoglobin, blood pressure, and random blood glucose for women age 15-49 years and men age 15-54 years, and the collection of finger-stick blood for HIV testing in a laboratory. Questionnaire information and biomarkers were collected only with informed consent from the respondents.

The NFHS-4 sample was designed to provide estimates of all key indicators at the national and state levels, as well as estimates for most key indicators at the district level (for all 640 districts in India, as of the 2011 Census). The total sample size of approximately 572,000 households for India was based on the size needed to produce reliable indicator estimates for each district and for urban and rural areas in districts in which the urban population accounted for 30-70 percent of the total district population. The rural sample was selected through a two-stage sample design with villages as the Primary Sampling Units (PSUs) at the first stage (selected

with probability proportional to size), followed by a random selection of 22 households in each PSU at the second stage. In urban areas, there was also a two-stage sample design with Census Enumeration Blocks (CEB) selected at the first stage and a random selection of 22 households in each CEB at the second stage. At the second stage in both urban and rural areas, households were selected after conducting a complete mapping and household listing operation in the selected first-stage units.

The figures of NFHS-4 and that of earlier rounds may not be strictly comparable due to differences in sample size and NFHS-4 will be a benchmark for future surveys. NFHS-4 fieldwork for Bihar was conducted in all 38 districts of the state from 16 March to 8 August 2015 by the Academic Management Studies (AMS) and collected information from 36,772 households, 45,812 women age 15-49 (including 7,464 women interviewed in PSUs in the state module), and 5,872 men age 15-54.

This report presents the key findings of the NFHS-4 survey in Bihar, followed by detailed tables and an appendix on sampling errors. At the time of finalization of this report, wealth quintiles for the country as a whole were not ready. Therefore, on finalization of the national report, the breakup of key indicators by wealth quintiles for all states will be provided as an additional document and uploaded on the official website of MoHFW and IIPS.

HOUSEHOLD CHARACTERISTICS

Household composition

More than one in 10 of Bihar's households (13%) are in urban areas. On average, households in Bihar are comprised of 5 members. Twenty-four percent of households are headed by women.

The vast majority of households in Bihar have household heads who are Hindu (84%). Sixteen percent of households have household heads who are Muslim.

Twenty-one percent of households in Bihar have household heads who belong to a scheduled caste, 58 percent belong to an other backward class (OBC), and a small proportion (3%) belong to a scheduled tribe. About one-fifth (18%) of Bihar's household heads do not belong to scheduled castes, scheduled tribes or other backward classes.

Thirty-nine percent of Bihar's population is under age 15; only 6 percent is age 65 and over. The overall sex ratio of the population is 1,062 females per 1,000 males, and the sex ratio of the population under seven years of age is much lower (939 females per 1,000 males). One-third of persons have an *Aadhaar* card.

Among children below 18 years of age, 4 percent have experienced the death of one or both parents. In all, 71 percent of children below 18 years of age live with both parents, 26 percent live with one parent (mostly with their mother), and the remaining 4 percent live with neither parent.

Births of a little over three-fifths of children (61%) under five years of age were registered with the civil authorities, and only 39 percent have a birth certificate.

Housing characteristics

Only 26 percent of households in Bihar live in a *pucca* house, and 58 percent live in semi-*pucca* house. Only 59 percent of households have electricity. As high as 67 percent of households do not use a sanitation facility, which means that household members practice open defecation, a small improvement from 75 percent at the time of NFHS-3. Open defecation is more common among rural households (73%) than urban households (22%).

Only four percent of households in Bihar have water piped into their dwelling, yard, or plot.

Almost all (98%) households use an improved source of drinking water, but only four percent have water piped into their dwelling, yard, or plot. Urban households (15%) are more likely than rural households (3%) to have water piped into their dwelling, yard or plot. Only 5 percent of households treat their drinking water to make it potable (mostly using a ceramic, sand or other water filter or an electronic purifier). Around 18 percent of households use a clean fuel for cooking.

Selected household possessions

Almost all urban and rural households in Bihar (95% and 89%, respectively) have a mobile phone. Seventy-two percent of households have a bank or post office account. BPL cards are held by 56 percent of households, up from 39 percent in NFHS-3. Agricultural land is owned by 46 percent of rural households and 20 percent of urban households. Overall, 43 percent of households in Bihar own agricultural land.

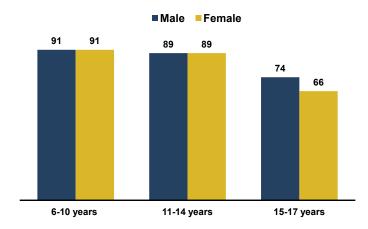

EDUCATION

School attendance among children

Eighty-four percent of children age 6-17 years in Bihar attend school (86% in urban areas and 84% in rural areas). School attendance is 89 percent at age 6-14 years, and then drops to 70 percent at age 15-17 years. There is no gender disparity in school attendance in the 6-14 year age group (89% for both boys and girls) and only a small difference in the age group 15-17 years (74% for boys and 66% for girls).

Are there gender differentials in children's school attendance?

Percentage of children attending school by age

Literacy, educational attainment and media exposure

In NFHS-4, literate persons are those who have either completed at least standard six or passed a simple literacy test conducted as part of the survey. According to this measure, 50 percent of women age 15-49 and 78 percent of men age 15-49 are literate.

Only 12 percent of women age 15-49 in Bihar have completed 12 or more years of schooling, compared with 26 percent of men.

Almost half of the women (48%) and 21 percent of men age 15-49 have never been to school. Only 12 percent of women age 15-49 in Bihar have completed 12 or more years of schooling, compared with 26 percent of men.

Media exposure is higher among men (68%) than women (40%). About 3 in 10 women and 44 percent of men watch television at least once a week. However, men (46%) are much more likely than women (16%) to read a newspaper or magazine at least once a week. Around one-third of men (32%) and 60 percent of women are not regularly exposed to print media or other forms of media.

FERTILITY

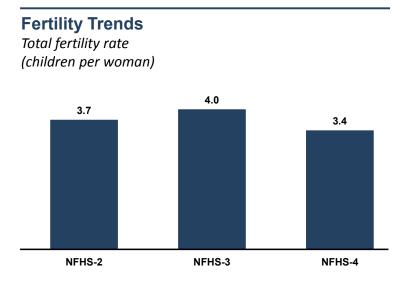

Age at first marriage

The median age at first marriage is 17.5 years among women age 20-49 years and 21.8 years among men age 25-49 years. On average, men get married more than four years later than women. Nearly half of the women age 20-24 years (42%) got married before the legal minimum age of 18, down from 69 percent in NFHS-3. Thirty-five percent of men age 25-29 years got married before the legal minimum age of 21, down from 43 percent of men in NFHS-3.

Fertility levels

The total fertility rate (TFR) in Bihar is 3.4 children per woman, among the highest in any state in India. Fertility decreased by 0.6 children in the 10 years between NFHS-3 and NFHS-4.

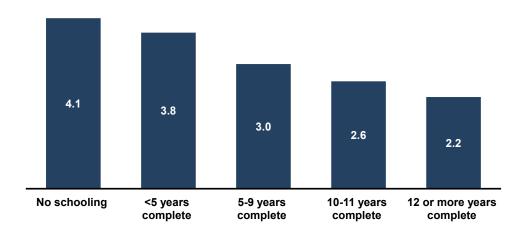

Fertility in urban areas is 2.4 children per woman, which is lower than in rural areas (3.6 children per woman). Among births in the three years preceding the survey, 24 percent were of birth order four or higher, compared with 36 percent in NFHS-3.

There are substantial differentials in fertility by urban-rural residence, religion, caste/tribe, and schooling. At current fertility rates, women with no schooling will have 1.9 children more than women with 12 or more years of schooling (a TFR of 4.1, compared with 2.2). Similarly, Muslim women will have almost one child more than Hindu women (a TFR of 4.1, compared with 3.3).

How does fertility vary with schooling?

Total fertility rate (children per woman)

Pregnancy outcome

Ninety-three percent of last pregnancies in the five years preceding the survey ended in a live birth, and the remaining seven percent terminated in foetal wastage (abortion, miscarriage, or stillbirth). Miscarriage is the most commonly reported type of foetal wastage, accounting for about 5 percent of all pregnancies, and abortions accounted more than 1 percent. A majority of abortions were performed in the private health sector (68%) and 9 percent were performed in the public health sector. Seventeen percent of women reporting an abortion, reported having complications from the abortion.

Teenage pregnancy

Among young women age 15-19 in Bihar, 12 percent have already begun childbearing, that is, they have already had a live birth or are pregnant with their first child, down substantially from 25 percent in NFHS-3. Three percent of women age 16 years have started childbearing, but this proportion increases sharply to 21 percent among women who are 18 years old and to 37 percent among women who are 19 years old. Young women who had no schooling are more than two times as likely to have begun childbearing as young women with 12 or more years of schooling.

Birth intervals

The median interval between births in the five years before the survey in Bihar is 29.1 months, one month shorter than in NFHS-3. Fourteen percent of births take place within 18 months of the last birth and 32 percent occur within 24 months. More than two-thirds of births (67%) occur within three years of the previous birth. Research shows that waiting at least three years between children reduces the risk of infant mortality.

More than two-thirds of births in Bihar occur within three years of the previous birth.

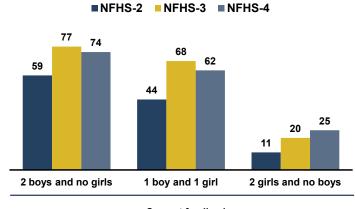

Fertility preferences

Fifty-eight percent of currently married women and 68 percent of currently married men want no more children. Among those who want another child, almost half (47% of women and 54% of men) would like to wait at least two years before the next birth. Fifty-one percent of women and 59 percent of men consider the ideal family size to be two or fewer children.

In Bihar there is a strong preference for sons. Thirty-seven percent of women and 30 percent of men want more sons than daughters, but only

How does son preference affect women's desire for children?

Percentage of currently married women with two children who want no more children

Current family size

2-4 percent of women and men want more daughters than sons. However, most men and women would like to have at least one son and at least one daughter.

Women's desire for more children is strongly affected by their current number of sons. For example, among women with two children, 74 percent with two sons and 62 percent with one son want no more children, compared with only 25 percent with two daughters. Notably, however, the proportion of currently married women with two children who want no more children irrespective of their number of sons has remained unchanged in the 10 years since NFHS-3. No matter how many children they already have, men are more likely than women to want no more children.

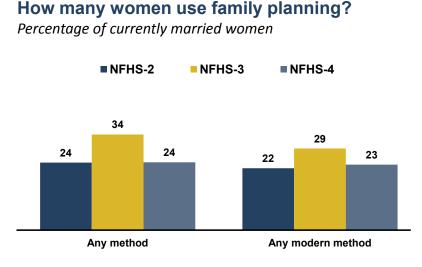

In Bihar, unplanned pregnancies are relatively common. If all women were to have only the number of children they wanted, the total fertility rate would have 2.5 children, instead of the current level of 3.4 children per woman.

FAMILY PLANNING

Contraceptive knowledge and use

Knowledge of contraception is almost universal in Bihar. However, some methods are still less well known. More than three-fourths of currently married women know about the pill, and 64 percent know about condoms/*Nirodhs*. Only 16 percent of currently married women know about female condoms. Among all women and men, 21 percent of women and 30 percent of men know about emergency contraception.

The contraceptive prevalence rate (CPR) among currently married women age 15-49 is 24 percent, down from 34 percent in NFHS-3. Modern method use, at 23 percent, also declined from its level in NFHS-3 (29%). The share of female sterilization in contraceptive method use is 86 percent, an increase from 70 percent in NFHS-3. In general, the use of spacing methods among women is very low. Contraceptive use in NFHS-4 generally increases with age, from only 2 percent for women age 15-19

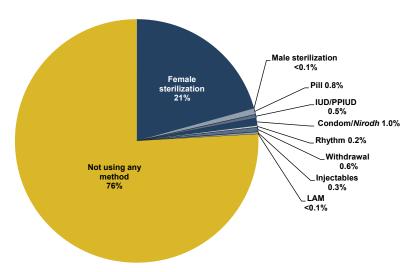

to 35 percent for women age 30-39. The contraceptive prevalence rate is unexpectedly low in some districts. Therefore, CPR results for these districts should be interpreted with caution.

In Bihar, contraceptive use is higher in urban areas (35%) than in rural areas (23%). Contraceptive prevalence does not vary greatly by schooling; however, 22 percent of currently married women with no schooling use female sterilization, compared with 15 percent of women with 12 or more years of schooling. Muslim women (11%) are much less likely to use contraception than Hindu women (26%).

Women in Bihar are much more likely to use contraception if they already have a son. For example, among women with two children, 27 percent with at least one son use a method of family planning, compared with 7 percent of women with two daughters and no sons.

Sixty-eight percent of sterilized women had their sterilization operation in a public sector health facility, mainly in a CHC/rural hospital/Block PHC, and 47 percent of IUD or PPIUD users had their IUD insertion in a public sector health facility.

What contraceptive methods do women use? Currently married women

The majority of users of injectables (84%), pills (83%) and condoms/ Nirodhs (77%) get their supply from the private sector health facility. Nonetheless, 47 percent IUD or PPIUD users, 14 percent each of pill and condom/Nirodh users separately get their supply from the public sector health facility.

The 12-month discontinuation rate for all methods is 21 percent. Almost three-fifths (58%) of users of modern spacing methods discontinued use within the first year after they adopted the method. The most common reason

for discontinuation is fertility related reasons other than wanting to become pregnant.

Almost three-fifths (58%) of users of modern spacing methods discontinued use within the first year after they adopted the method.

Informed choice

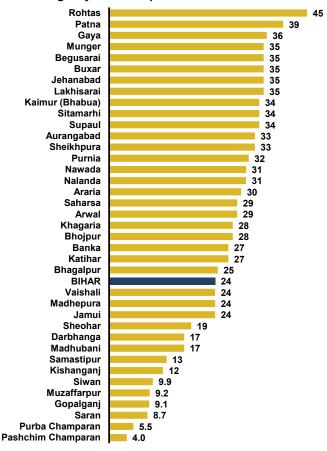

Women who know about all available contraceptive methods and their side effects can make better choices about what method to use. Only 40 percent of users of selected modern contraceptive methods were ever told by a health or family planning worker about other methods they could use. Only 34 percent were told about the possible side effects or problems with their method, and even fewer (27%) were told what to do if they experienced any side effects.

Men's attitudes

Forty-two percent men age 15-49 in Bihar agree that contraception is women's business and a man should not have to worry about it. However, only 16 percent think that women using contraception may become promiscuous. A large majority of men (55%) know that a condom, if used correctly, protects against pregnancy most of the time.

Contraceptive Prevalence Rate by District

Percentage of currently married women

Unmet need

Unmet need for family planning is defined as the percentage of currently married women who either want to space their next birth or stop childbearing entirely, but are not using contraception. According to this definition, 21 percent of currently married women have an unmet need for family planning, slightly lower than the 24 percent in NFHS-3. Currently, 53 percent of the demand for family planning is being satisfied (down from 59% in NFHS-3), and 51 percent of the demand is being satisfied by modern methods.

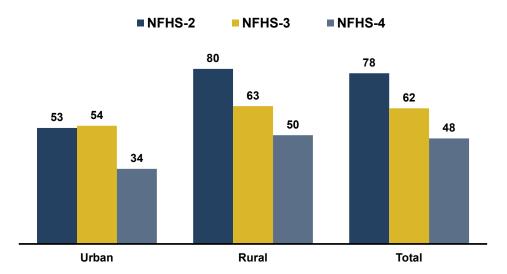

INFANT AND CHILD MORTALITY

The infant mortality rate in Bihar in NFHS-4 is estimated at 48 deaths before the age of one year per 1,000 live births, down from the NFHS-3 estimate of 62, and the NFHS-2 estimate of 78. The under-five mortality rate for Bihar is 58 deaths per 1,000 live births, down substantially from the NFHS-3 estimate of 85 and the NFHS-2 estimate of 112.

As expected, boys have a slightly higher mortality rate than girls during the neonatal period (in the first month of life). Girls have higher mortality rates than boys between ages 1 and 5 years.

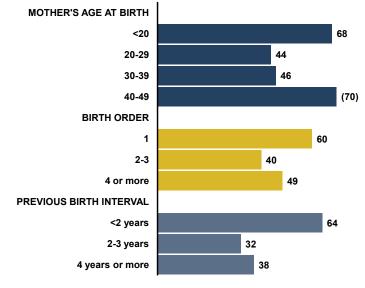

Trends in Infant Mortality

Deaths per 1,000 live births

Children born to mothers under age 20 are more likely to die during infancy than children born to mothers in the prime childbearing age (20-29 years). Infant mortality is 68 per 1,000 live births for teenage mothers compared with 44 per 1,000 live births for mothers age 20-29 and 46 per 1,000 live births for mothers age 30-39. Having children too close together is especially risky. Children born less than two years after a previous birth are about two times as likely to die in infancy as children whose mothers waited two or more years between births.

Infant mortality rates are higher for Hindus than for Muslims and are higher for scheduled castes (60 per 1,000 live births), scheduled tribes and other backward classes (47 per 1,000 live births each) than for those who are not from scheduled castes, scheduled tribes, or other backward classes (35 per 1,000 live births).

The infant mortality rate is considerably higher in rural areas than in urban areas. The infant mortality rate is much higher for children whose mothers have no schooling (51 per 1,000 live births) than for children whose mothers have completed 10 or more years of schooling (37 per 1,000 live births).

Children born less than two years after a previous birth are about two times as likely to die in infancy as children whose mothers waited two or more years between births.

MATERNAL HEALTH

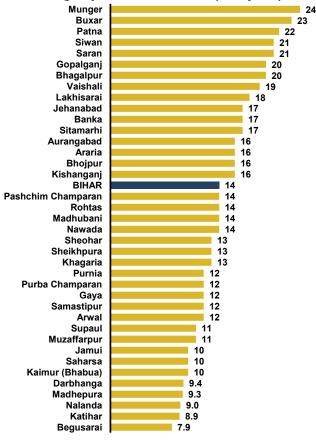

Antenatal care

Among mothers who gave birth in the five years preceding the survey, almost half received antenatal care (ANC) for their last birth from a health professional (30% from a doctor and 19% from an auxiliary nurse midwife (ANM), lady health visitor (LHV), nurse, or midwife). Fortyfour percent did not receive any antenatal care. Among mothers who gave birth in the five years preceding the survey, almost two-thirds (65%) registered the pregnancy for the most recent live birth. Among the registered pregnancies, four-fifths (80%) received a Mother and Child Protection Card (MCP Card).

Just over one-third of women (35%) received antenatal care during the first trimester of pregnancy, as is recommended. Only 14 percent of mothers had four or more antenatal care visits. Urban women were twice as likely to receive four or more antenatal visits as rural women. The proportion of women who had their first antenatal care visit in the first trimester of pregnancy for their last births increased substantially in the 10 vears since NFHS-3. For percent of their last births, mothers received iron and folic acid (IFA) supplements, but only 10 percent consumed them for the recommended 100 days or more. Ninety percent of last births were protected against neonatal tetanus through tetanus toxoid vaccinations given to the mother. Nine percent of mothers took an intestinal parasite drug during pregnancy.

Four or More Antenatal Care Visits by District

Percentage of last births in the past five years

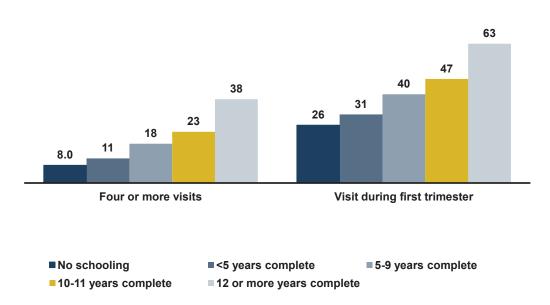

Only 14 percent of mothers in Bihar received at least four antenatal care visits for their last birth.

Among women with a live birth in the five years preceding the survey who met with a community health worker in the last three months of pregnancy for their most recent live birth, at least half received advice on each of the five different areas (70% received advice on the importance of institutional delivery, 68% on breastfeeding, 64% on keeping the baby warm, 61% on cord care, and 53% on family planning).

How does appropriate antenatal care vary with schooling?

Percentage of last births in the past five years

Even when women receive antenatal care, sometimes they do not receive all the services needed to monitor their pregnancy. In Bihar, at least three-fifths of women who received antenatal care for their last birth received each of the services needed to monitor their pregnancy: having their weight taken (77%), having their abdomen examined and blood pressure measured (71-72%), having a urine sample taken (70%), and having a blood sample taken (62%).

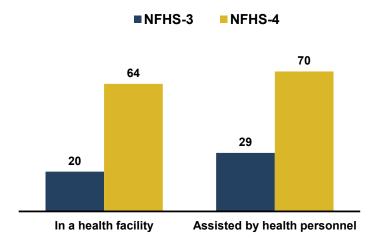

An ultrasound test was performed during 31 percent of pregnancies in the five years preceding the survey. Women with at least 12 years of schooling were much more likely to have an ultrasound test (64%) than women with no schooling (19%). Pregnant women with no sons were much more likely to have an ultrasound test than those with at least one son. For example, women with two children and no sons who had an ultrasound test during their next pregnancy were almost twice as likely to have a son as to have a daughter for their third child. These results indicate that sex-selective abortion is common in Bihar.

Delivery care

Sixty-four percent of births take place in a health facility (mostly a government facility) and 36 percent take place at home. The percentage of births in a health facility more than tripled in the 10 years between NFHS-3 and NFHS-4, from 20 percent in NFHS-3 to 64 percent in NFHS-4. Institutional births are more common among women who have received an antenatal check, women with 12 or more years of schooling, women who are having their first birth, and Hindu women.

Are babies being delivered safely?

Percentage of births in the past five years

For 98 percent of home births, a clean blade was used to cut the cord, as is recommended. A disposable delivery kit was used for 50 percent of deliveries. Eighty-five percent of home births followed the recommendation that the baby be immediately wiped dry and then wrapped without being bathed first.

Seventy percent of births during the past five years took place with assistance from a skilled provider, and another 19 percent were delivered by a traditional birth attendant.

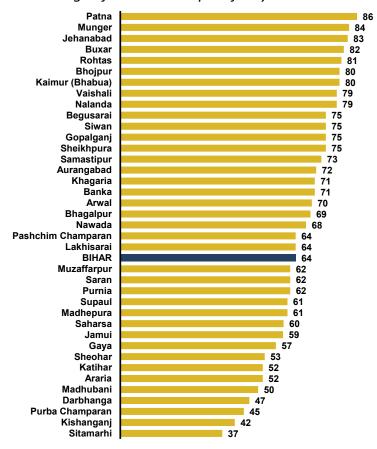

Six percent of births during the past five years were delivered by caesarean section. Sixty percent of caesarean sections (4% of all births) were emergency caesarean sections.

Among women who had a live birth in the five years preceding the survey that was delivered in a health facility, 54 percent received financial assistance under the *Janani Suraksha Yojana* (JSY) for their most recent birth. Rural women were more likely than urban women to receive financial assistance under JSY. Scheduled caste women were more likely than women belonging to any other caste/tribe group to receive financial assistance under JSY. Women with no schooling were twice as likely as women with at least 12 years of schooling to receive financial assistance under JSY.

Sixty-four percent of children in Bihar who were born in the last five years were born in a health facility.

Institutional Delivery by District

Percentage of births in the past five years

Postnatal care

Early postnatal care for a mother helps safeguard her health and can reduce maternal mortality. In Bihar, 49 percent of mothers had a postnatal check after their last birth and 46 percent of mothers had a postnatal check within two days of the birth, as is recommended. Postnatal care is most common following births in a medical facility; 58 percent of births in public health facilities and 73 percent of births in private health facilities were followed by a postnatal check for the mother within two days of birth, compared with only 14 percent of home births.

Only 14 percent of last births in the five years preceding the survey received a health check in the first two days after birth. Only 9 percent of home births received a health check in the first two days after birth.

Male involvement in maternal care

Sixty-three percent of men with a child under three years of age said that the youngest child's mother received antenatal care. Forty-four percent of men with a child under three years said they were present during at least one antenatal check received by the child's mother (62% in urban areas and 41% in rural areas), but only 32 percent were told by a health provider or health worker what to do if the mother had a pregnancy complication. Only 28-44 percent of men were told about the signs of specific pregnancy complications (yaginal bleeding,

convulsions, high blood pressure, prolonged labour, and severe abdominal pain).

Among fathers with a child less than three years of age, 41-53 percent were given information by a health provider or worker about various aspects of maternal care. Fifty-three percent were told about the importance of proper nutrition for the mother during pregnancy and 44 percent were told about the importance of delivering the baby in a health facility. Forty-one percent were told about family planning or delaying the next child by a health provider or a health worker. Only 30-43 percent of fathers whose child was not delivered in a health facility were told about the importance of cord care, the importance of keeping the baby warm immediately after birth, and the importance of breastfeeding the baby immediately after delivery.

CHILD HEALTH

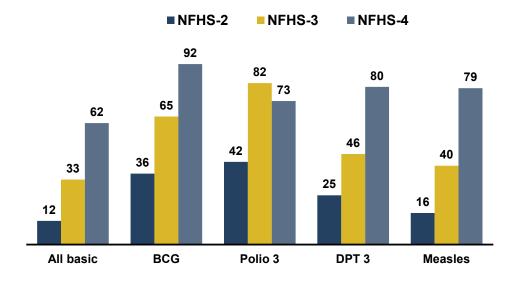

Vaccination of children

Less than two-thirds (62%) of children age 12-23 months received all basic vaccinations against six major childhood illnesses (tuberculosis, diphtheria, pertussis, tetanus, polio, and measles) at any time before the survey. However, most children are at least partially vaccinated; only 7 percent have not received any vaccinations at all.

Ninety-two percent of children have received a BCG vaccination. However, only about three-quarters have received other basic vaccinations (73% have received at least the recommended three doses of polio vaccine, 79% have been vaccinated against measles, and 80% have received the three recommended doses of DPT vaccine). There is considerable dropout between the first and third doses of DPT vaccine (from 90% to 80%) and polio vaccine (from 90% to 73%).

Trends in Vaccination Coverage

Percentage of children 12-23 months receiving vaccinations

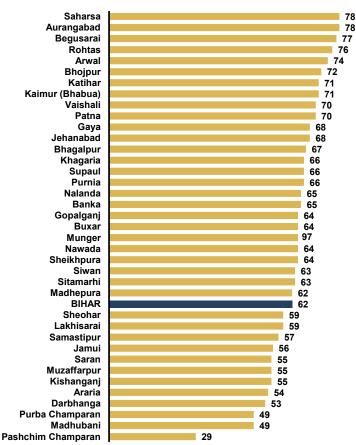

16

Between NFHS-3 and NFHS-4, there was a considerable increase in vaccination coverage for three doses of DPT (from 46% to 80%), measles (from 40% to 79%), and BCG (from 65% to 92%), but coverage for three doses of polio vaccine declined from 82 percent to 73 percent. Overall, there has been a substantial increase in the coverage of all basic vaccinations (from 33% to 62%). In addition, 84% have received at least one dose of hepatitis B vaccine, two-thirds of children (66%) have received all three recommended doses of hepatitis B vaccine.

Coverage of All Basic Vaccinations by District

Percentage of children 12-23 months

The coverage with all basic vaccinations is higher for children of first birth order (65%) than higher birth orders. There is not much difference in vaccination coverage by the sex of the child or urban-rural residence. Muslim children have the lower vaccination coverage than Hindu children (52% versus 64%). Among all population subgroups, children whose mothers have completed 12 or more years of schooling have the highest coverage with all basic vaccinations (71%).

Coverage with all basic vaccinations is highest for children whose mothers have completed 12 or more years of schooling.

Childhood illnesses

In the two weeks before the survey, 3 percent of children under age five years had symptoms of an acute respiratory infection (cough accompanied by (1) short, rapid breathing that is chest-related and/or (2) difficult breathing that is chest related). Of these children, 68 percent were taken to a health facility or health provider.

Twelve percent of children under age five were reported to have had fever in the two weeks preceding the survey; 60 percent of these children were taken to a health facility or provider for advice or treatment.

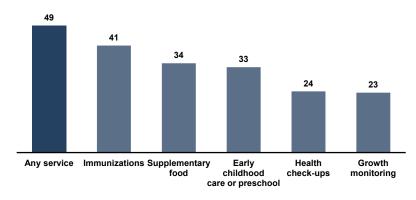

Overall, 10 percent of children under age five years had diarrhoea in the two weeks preceding the survey. Fifty-five percent of these children were taken to a health facility or health provider. Seven out of 10 mothers of young children have heard of oral rehydration salt (ORS) packets for the treatment of diarrhoea, but only 45 percent of children with diarrhoea were given oral rehydration salt (ORS) packets for the treatment of diarrhoea. Twenty-nine percent of children with diarrhoea were given gruel and a little more than half (56%) were given some type of oral rehydration therapy (ORT). Twenty percent were given zinc supplements. Twenty-two percent of children with diarrhoea did not receive any type of treatment at all.

To reduce dehydration and minimise the effects of diarrhoea on nutritional status, it is recommended that normal feeding of children be continued when they have diarrhoea and that the amount of fluids given should be increased. However, in Bihar only 4 percent of children with diarrhoea received more to drink than normal. Only about one-third of children (32%) received the same amount to drink as usual. Of greater concern, almost two-thirds of children (63%) with diarrhoea were given less to drink or nothing at all to drink. Only 31 percent of children with diarrhoea were given the same amount of food or more food, as recommended. Two-thirds of children with diarrhoea (36%) were given ORT and continued feeding.

Integrated Child Development Services (ICDS)

How many children received anganwadi centre services?

Percentage of age-eligible children receiving services

The ICDS programme provides nutrition and health services for children under age six years and pregnant or breastfeeding women, as well as preschool activities for children age 3-5 years. These services are provided through community-based anganwadi centres.

Forty-nine percent of children under 6 years receive services of some kind from an *anganwadi* centre. The most common services that age-eligible children receive are immunizations (41%), supplementary food (34%),

and early childhood care or preschool (33%). The services that are least likely to be accessed are growth monitoring and health check-ups (23-24%). Half of the mothers of children who were weighed at an *anganwadi* centre received counseling from an *anganwadi* worker or an ANM. Among children under 6 years, slightly more than one-third of their mothers (35-37%) received any services from an *anganwadi* centre during pregnancy and while breastfeeding.

BREASTFEEDING, NUTRITION, AND ANAEMIA

Infant feeding

Although breastfeeding is nearly universal in Bihar, only 54 percent of children under 6 months are exclusively breastfed, as the World Health Organization (WHO) recommends. Eighty-one percent are put to the breast within the first day of life, but only 35 percent started breastfeeding in the first hour of life (as recommended). While the initiation of breastfeeding indicators show substantial improvement since NFHS-3, many infants are still deprived of the highly nutritious first milk (colostrum) and the antibodies it contains.

It is recommended that nothing be given to children other than breastmilk even in the first three days when the milk has not begun to flow regularly because prelacteal feeds limit the frequency of suckling by the infant and exposes the baby to the risk of infection. However, one-fourth of children are given something other than breastmilk during the first three days. Overall, 89 percent of children continue breastfeeding at 1 year and 77 percent continue breastfeeding at 2 years.

After the first 6 months, breastmilk is no longer enough to meet the nutritional needs of infants. Therefore, complementary foods should be added to the diet of the child. However, at age 6-8 months only about one-third of children (31%) in Bihar receive breastmilk and complementary foods.

WHO has several recommendations for infant and young child feeding (IYCF) practices for children age 6-23 months. The key IYCF indicators measure the adequacy of dietary diversity and meal frequency for breastfed and nonbreastfed children. Less than one-third of children age 6-23 months (30%) are fed the recommended minimum number of times per day and even fewer (18%) are fed from the appropriate number of food groups. Only 8 percent are fed according to all three recommended practices.

Micronutrient deficiency is a major contributor to childhood morbidity and mortality. Vitamin A is an essential nutrient for the immune system. Severe vitamin A deficiency (VAD) can cause eye damage and a higher risk of dying from measles and diarrhoeal disease. The Government of India recommends that children under 5 years of age receive vitamin A supplements every six months, starting at age 9 months. In Bihar, 62 percent of children age 9-59 months were given a vitamin A supplement in the past six months, but only 46 percent of children age 9-23 months ate vitamin A-rich foods during the day or night before the survey.

Iron deficiency is a primary cause of anaemia. Eating foods rich in iron and taking iron supplements can help prevent anaemia. Only 16 percent children age 9-23 months ate iron-rich foods during the day or night before the survey, but 22 percent of children age 6-59 months were given iron supplements in the week before the survey.

Children's nutritional status

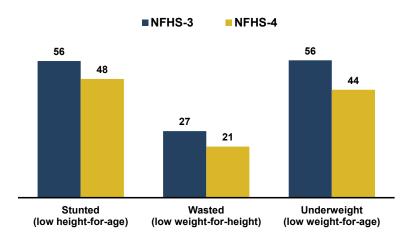

Forty-eight percent of children under age five years are stunted, or too short for their age, which indicates that they have been undernourished for some time. Twenty-one percent are wasted, or too thin for their height, which may result from inadequate recent food intake or a recent illness causing weight loss, and 7 percent are severely wasted. Forty-four percent are underweight, which takes into account both chronic and acute undernutrition. Even during the first six months of life, when almost all babies are breastfed, 19 percent of children are stunted, 30 percent are underweight, and 31 percent are wasted.

Children's nutritional status in Bihar has improved since NFHS-3 by all measures. Stunting decreased from 56 percent to 48 percent in the 10 years between NFHS-3 and NFHS-4, and the percentage of children who are underweight decreased from 56 percent to 44 percent. However, in the same period, wasting decreased from 27 percent to 21 percent. Despite the gains in and underweight, wasting malnutrition is still a major problem in Bihar.

There are only small differences in the level of undernutrition by the sex of the child, religion, or the child's

Trends in Children's Nutritional Status

Percentage of children under five years

Note: Nutritional status estimates are based on the 2006 WHO International Reference Population

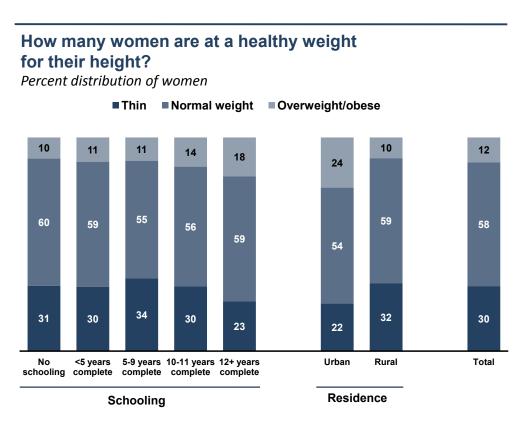

living arrangements. However, differences are more pronounced for other background characteristics. Undernutrition generally decreases with increasing mother's schooling, better nutritional status of the mother, and larger child's size at birth. Stunting and underweight are higher in rural areas than in urban areas.

Adults' nutritional status

More than two-fifths of women (42%) and 38 percent of men are either too thin or overweight or obese. More men and women are thin than overweight or obese, which is the same as the pattern in NFHS-3. Thirty percent of women and 25 percent of men in Bihar are too thin (which represents a substantial improvement since NFHS-3, but the percentage overweight or obese has approximately doubled to 13 percent of men and 12 percent of women. About threefifths of women and men are at a healthy weight for their height.

Undernutrition is particularly common in the younger age groups, in rural areas, and among the scheduled caste women. Overweight and obesity are most prevalent in older adults, those in urban areas, and those who are well-educated. Because population groups that are less likely to be too thin are the same groups that are more likely to be overweight or obese, the percentage suffering from either of these two nutritional problems is fairly constant across many groups, regardless of their educational attainment, caste, age, residence, or marital status.

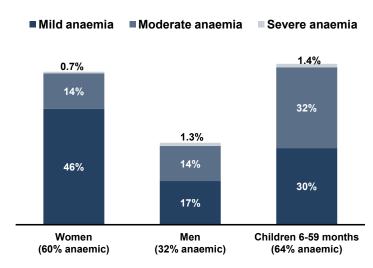

The use of iodized salt prevents iodine deficiency, which can lead to miscarriage, goitre, and mental retardation. More than 90 percent of Bihar's households (94%) were using iodized salt at the time of the survey, almost the same proportion (95%) as reported in NFHS-3.

Anaemia

Anaemia is a condition that is marked by low levels of haemoglobin in the blood. Iron deficiency is estimated to be responsible for about half of all anaemia globally, but anaemia can also be caused by malaria, hookworm and other helminths, other nutritional deficiencies, chronic infections, and genetic conditions. Anaemia can result in maternal mortality, weakness, diminished physical and mental capacity, increased morbidity from infectious diseases, perinatal mortality, premature delivery, low birth weight, and (in children) impaired cognitive performance, motor development, and scholastic achievement. Anaemia is a major health problem in Bihar, especially among women and children.

Anaemia among women, men, and children

Among children between the ages of 6 and 59 months, a large majority (64%) are anaemic. This includes 30 percent who are mildly anaemic, 32 percent who are moderately anaemic, and 1 percent who suffer from severe anaemia. Girls are slightly more likely than boys to have anaemia. Children of mothers who have anaemia are much more likely to be anaemic. Although anaemia levels vary somewhat according to background characteristics, anaemia among children is widespread in every group. More than half of children (54%) in Bihar are anaemic even if their mother has 12 or more years of schooling.

Sixty percent of women in Bihar have anaemia, including 46 percent with mild anaemia, 14 percent with moderate anaemia, and 1 percent with severe anaemia. Anaemia is particularly high for women who are breastfeeding, but anaemia exceeds 57 percent for every group of women. Almost one-third of men (32%) are anaemic. Men under age 20 and men with no schooling are particularly likely to be anaemic.

ADULT HEALTH AND HEALTH CARE

Tuberculosis

In Bihar, 637 persons per 100,000 are estimated to have medically treated tuberculosis, based on reports from household respondents. The prevalence of medically treated tuberculosis is higher among men (773) than among women (509) and is higher in rural areas (665) than in urban areas (446). The prevalence of tuberculosis rises rapidly with the respondent's age.

A large majority of respondents have heard of tuberculosis (81% of women and 86% of men), but even among those who have heard of tuberculosis, only 58 percent of women and 66 percent of men know that it is spread through the air by coughing or sneezing. Over three-fifths of women (61%) and 56 percent of men have misconceptions about how tuberculosis is spread. Overall, 91 percent of women and 93 percent of men know that tuberculosis can be cured, and only 11 percent each of women and men say that if a family member had tuberculosis, they would want to keep it a secret.

Diabetes, asthma, goitre, heart disease, and cancer

According to self-reports, 1,554 women and 1,291 men age 15-49 per 100,000 have diabetes. Overall, 1,799 women and 1,360 men age 15-49 per 100,000 suffer from asthma. The prevalence of asthma is generally higher among older age groups, those who have low education, and those in rural areas. Goitre or any other thyroid disorder is somewhat less common than asthma (1,240 cases per 100,000 women and 469 cases per 100,000 men). The prevalence of any

heart disease is over one and a half times as high among women (2,269 per 100,000) as among men (1,472 per 100,000). Among the five diseases, cancer is the least common, with 609 women per 100,000 and 131 men per 100,000 reportedly suffering from cancer.

Blood pressure (hypertension)

Eight percent of women age 15-49 in Bihar have hypertension, including 4 percent with Stage 1 hypertension, and 1 percent each with Stage 2 and Stage 3 hypertension. A little over two-third of women (69%) have normal blood pressure including, 2 percent of women with normal blood pressure who are taking medicine to lower their blood pressure. The prevalence of hypertension among men age 15-49 is somewhat higher than among women. Eleven percent of men age 15-49 in Bihar have hypertension, including 8 percent with Stage 1 hypertension, 1 percent with Stage 2 hypertension, and 0.5 percent with Stage 3 hypertension. Fifty-one percent of men have normal blood pressure including, 1 percent of men with normal blood pressure who are taking medicine to lower their blood pressure. For both women and men, hypertension increases steadily with age.

Blood glucose

NFHS-4 included measurement of random blood glucose among women age 15-49 and men age 15-54. Two percent of women age 15-49 in Bihar have high blood glucose levels, and another 2 percent have very high blood glucose levels. In comparison, 3 percent of men age 15-49 each have high and very high blood glucose levels. Older women and men have relatively high blood glucose levels.

Health examinations

In Bihar, 12 percent of women have ever undergone an examination of the cervix, 5 percent have ever undergone a breast examination, and 6 percent have ever undergone an examination of the oral cavity.

Tobacco and alcohol use

Half of men, but only 3 percent of women, age 15-49 use some form of tobacco. Men are much more likely to use *khaini* (37%), smoke cigarettes (15%), use *gutkha* or *paan masala* with tobacco (11%), and chew *paan* with tobacco (11%) than to use other types of tobacco. Among men, the overall use of tobacco is higher in rural areas than in urban areas, with *khaini* being especially popular in rural areas. One in 11 men who smoke cigarettes or *bidis* smoked 10 or more cigarettes or *bidis* in the past 24 hours. Men are less likely to drink alcohol (29%) than to use tobacco, and almost no women say that they drink alcohol. Among men who drink alcohol, half drink alcohol at least once a week.

Source of health care

The private medical sector is the main source of health care for more than seven-tenths of both urban and rural households. Household members are much more likely to go to private doctors or clinics (50%) than private hospitals (15%).

Health insurance

Despite the emergence of a number of health insurance programmes and health schemes, only 12 percent of households in Bihar have any kind of health insurance that covers at least one usual member of the household. Health insurance coverage is somewhat more common in rural areas (13%) than in urban areas (10%). In Bihar, four types of programmes dominate: the *Rashtriya Swasthya Bima Yojana* (RSBY), with many fewer households using the State health insurance scheme, the Central Government Health Scheme (CGHS), and the Employees' State Insurance Scheme (ESIS).

Only 8 percent of women and 6 percent of men age 15-49 years in Bihar are covered by any health scheme or health insurance. More women and men in rural areas than in urban areas are covered by any health scheme or health insurance. Health scheme or health insurance coverage is higher among women with no schooling or less than five years of schooling than among those with 12 or more years of schooling.

HIV/AIDS

Awareness of HIV or AIDS

Only 46 percent of women in Bihar have heard of HIV or AIDS. In urban areas, 67 percent know about HIV or AIDS, compared with 42 percent in rural areas. Older women age 40-49 years are least likely (41%) to have heard of HIV or AIDS. Women having no schooling (29%), women not having regular exposure to media (34%) and scheduled tribe women (34%) are less likely than other women to have heard of HIV or AIDS.

Men are much more likely than women to know about HIV or AIDS. Over four-fifths of men (81%) in Bihar have heard of HIV or AIDS, including 89 percent in urban areas.

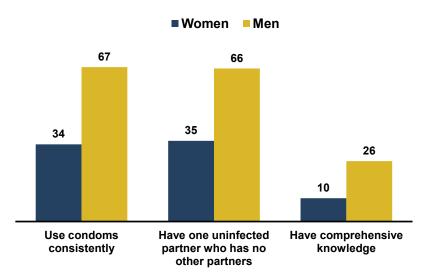

Knowledge of prevention and transmission

Men are much more likely than women to know how HIV is transmitted and how to keep from getting it. For example, only 34 percent of women know that consistent condom use can help prevent HIV/AIDS, compared with 67 percent of men, and only about one-third of women (35%) know that having just one uninfected partner who has no other partners can reduce the chance of getting HIV/AIDS, compared with 66 percent of men.

Only 10 percent of women and 26 percent of men in Bihar have a 'comprehensive knowledge' about HIV/AIDS. This means they know that consistent use of condoms every time they have sex and having just one uninfected sex partner who has no other partners can reduce the chance of getting HIV/AIDS, they know that a healthy-looking person can have HIV/AIDS, and they reject two common misconceptions about transmission or prevention of HIV/AIDS.

Do people know how to prevent HIV/AIDS?

Percentage of women and men age 15-49

HIV-related stigma

Four-fifths (80%) of women and 83 percent of men in Bihar would be willing to take care of a relative with HIV/AIDS in their home. A similar proportion of women (76%) and men (74%) say that a female teacher who has HIV/AIDS but is not sick should be allowed to continue teaching. About seven-tenths of adults say that they would buy fresh vegetables from a shopkeeper with HIV/AIDS. Two-thirds of women and 73 percent of men say that if a family member got infected with HIV/AIDS, they would not want to keep it a secret.

HIV testing prior to NFHS-4, blood transfusions, and safe injections

Only 3 percent of women and 4 percent of men age 15-49 had ever been tested for HIV prior to NFHS-4. Women and men living in urban areas are somewhat more likely to have ever been tested for HIV prior to NFHS-4 than rural women and men. Only 6 percent of women who had a live birth in the past five years and received ANC during pregnancy were tested for HIV during ANC. Urban women (11%) are more likely than rural women (6%) to have been tested for HIV during ANC.

Only 6 percent of women who had a live birth in the past five years and

received ANC during pregnancy were tested for HIV during ANC.

In Bihar, women (3%) are somewhat more likely than men (1%) to have ever had a blood transfusion. Women are also more likely than men to have received an injection in the past 12 months (44% of women, compared with 41% of men).

For almost nine-tenths of adults (86%) who received an injection in the past 12 months, a disposable syringe was used.

SEXUAL BEHAVIOUR

NFHS-4 included questions on respondents' sexual behaviour. Respondents were asked about their age at first sex, their current and previous sexual partners, higher-risk intercourse and condom use. In addition, men were asked whether they had paid for sex in the past year. These questions are sensitive and subject to reporting bias, so the results should be interpreted with caution.

Higher-risk behaviour

Higher-risk sex is sexual intercourse with someone who is neither a spouse nor a cohabiting partner. Among those who had sex in the past 12 months, only 0.3 percent of women and 5 percent of men reported having had higher-risk sex during the past 12 months. The percentage of men who had higher-risk sexual intercourse in the past 12 months is somewhat higher (6%) in urban areas than in rural areas (5%). Even fewer respondents said that they had multiple sex partners in the past 12 months (0.8% of women and 3% of men). Almost one-fourth of men (23%) who had higher-risk sex in the past 12 months reported using a condom the last time they had higher-risk sex.

One percent of men said they paid for sex in the past year. Twenty-two percent of the men who paid for sexual intercourse in the past 12 months used a condom the last time they paid for sexual intercourse.

Women's Empowerment

Women's hygiene

Using a hygienic method of menstrual protection is important for women's health and personal hygiene. In NFHS-4, young women age 15-24 were asked what method or methods they use for menstrual protection, if anything. In Bihar, 82 percent use cloth, 16 percent use sanitary napkins, 14 percent use locally prepared napkins, and 2 percent use tampons. Overall, 31 percent of women age 15-24 use a hygienic method of menstrual protection. Women with at least 12 years of schooling are six times as likely to be using a hygienic method as women with no schooling or less than five years of schooling. Notably, only 27 percent of rural women use a hygienic method of menstrual protection, compared with 56 percent of urban women.

Employment and earnings

Only 20 percent of women age 15-49 were employed in the 12 months preceding the survey; in the same period, 76 percent of men age 15-49 were employed. Among employed women, 62 percent earned cash, including 15 percent whose earnings were in both cash and in-kind, and 22 percent were not paid at all. Most men who were employed earned cash (87%) and only 10 percent were not paid at all. Fifty percent of employed women worked in non-agricultural occupations, compared with 62 percent of employed men.

Only 20 percent of women age 15-49 were employed in the 12 months preceding the survey.

Among currently married women who work and are paid in cash, 83 percent decide how their earnings will be used, either alone or jointly with their husbands. Over one-third (34%) of women who work for cash say that they earn more or about the same as their husbands. By contrast, 81 percent of currently married men who have wives who have cash earnings report that they alone or jointly with their wives decide how her earnings are used and 45 percent of men who have cash earnings and whose wives have cash earnings say that their wife earns more or about the same as them.

Decision making

Currently married women were asked who makes decisions about their own health care, major household purchases, and decision about visits to their own family or relatives. Women are slightly more likely to participate in decisions about their own health care (66%) than in decisions about major household purchases and visits to their own family and relatives (61-64%). Overall, 52 percent of currently married women participate in making all three of these decisions, and 25 percent do not participate in making any of the three decisions. Participation in all three decisions varies most by age, increasing sharply from 37 percent among women age 15-19 to 59 percent among women age 40-49.

Currently married men were also asked who makes decisions about their own health care and major household purchases. Men were much more likely than women to report that they alone or jointly with their wife participated in both these decisions: 89 percent participated in making decisions about their own health care and 95 percent participated in decisions about major household purchases.

Other indicators of women's empowerment

Only 33 percent of women have some money that they can decide how to use. The proportion of women with money which they control is higher among urban than rural women, increases sharply with age, and is higher among women who are employed for cash (52%) than any other group of women.

About one-fourth of women (26%) have a bank or savings account that they themselves use. This percentage is highest, at 45 percent, among women who have 12 or more years of schooling. Women's knowledge and use of microcredit programmes is very limited. Twenty-eight percent of women know of a microcredit programme in the area and only 5 percent have ever taken a loan from a microcredit programme.

About one-fourth of women (26%) have a bank or savings account

that they themselves use.

Only 34 percent of women are allowed to go by themselves to all three of the following places: the market, a health facility, and places outside the village/community. The only groups of women in which more than half are allowed to go to all three places alone are women age 40-49 and employed women who earn cash.

Ownership of assets

Fifty-eight percent of women and 77 percent of men own a house alone or jointly with someone else, and 50 percent of women and 67 percent of men own land alone or jointly with someone else. Ownership of both a house and land is more common in rural than urban areas for both women and men.

Fifty-eight percent of women own a house alone or jointly with someone else, and 50 percent of women own land alone or jointly with someone else.

Over two-fifths of women (41%) have a mobile phone that they themselves use, and among women who have a mobile phone that they themselves use 42 percent can read SMS messages. Fifty percent of urban women have a mobile phone they themselves can use, compared with 39 percent of rural women. Only 34 percent of scheduled caste women have a mobile phone they can use, compared with more than two-fifths of women belonging to other backward class and 48 percent of women not belonging to scheduled castes, scheduled tribes and other backward classes. Scheduled caste women and scheduled tribe women who have a mobile phone that they can use are also much less likely to be able to read SMS messages than women in other caste groups who have a mobile phone that they can use.

Forty-one percent of women have a mobile phone that they themselves use.

Gender-role attitudes

Fifty-three percent of women believe it is justifiable for a husband to beat his wife under some circumstances. Women are most likely to believe that wife-beating is justified if a woman shows disrespect for her in-laws (39%), followed by if she argues with her husband (34%) and if she neglects the house or children (33%). Men are less likely to agree: 38 percent say that wife-beating is justified in some circumstances, especially if the wife shows disrespect for in-laws (24%) or if she argues with him (21%) and the husband suspects his wife is unfaithful (19%). Even among women and men who have completed at least 12 years of schooling, 36 percent of women and 29 percent of men say that a husband is justified in beating his wife for one or more of the specified reasons.

Seventy-two percent of women and 52 percent of men believe that a woman is justified in refusing to have sex with her husband if she knows he has a sexually transmitted disease, if she knows he has intercourse with other women, and if she is tired or not in the mood. Most men, 80 percent, do not agree that if a wife refuses to have sex with her husband he has a right to get angry and reprimand her, refuse to give her financial support, use force to have sex even if she doesn't want to, or have sex with another woman.

DOMESTIC VIOLENCE

Among women age 15-49, 37 percent have ever experienced physical violence and 12 percent have ever experienced sexual violence. In all, 39 percent of women in Bihar have experienced physical or sexual violence. Among those who experienced physical violence since age 15, the most common perpetrator for ever-married women was the husband (95%) and for never-married women, it was a mother/step-mother (59%), sister/brother (37%), father/step-father (18%), or teacher (14%).

Almost two-fifths of women age 15-49 in Bihar have experienced physical or sexual violence.

Violence during pregnancy

One in 20 women who have ever been pregnant have ever experienced physical violence during one or more of their pregnancies. Women who are widowed, divorced, separated, or deserted (9%) and women belonging to scheduled caste, urban women, and women with 5 or more children (7% each) are more likely than women in any other group to have experienced violence during pregnancy.

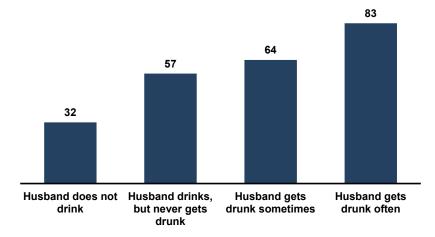

Spousal violence

Thirty-seven percent of ever-married women report having been slapped by their husband; 13-22 percent report being pushed, shaken, or having something thrown at them; having their arm twisted or hair pulled; being punched; or being kicked, dragged, or beaten up; 3 percent have been choked or burned on purpose and 1 percent have been threatened or attacked with a knife, gun, or any other weapon. Eleven percent report that their husbands have physically forced them to have sex even when they did not want to, and 7 percent report that their husband forced them with threats or other ways to perform sexual acts they did not want to perform. Overall, 43 percent of ever-married women have experienced spousal physical or sexual violence from their current husband or, if not currently married, from their most recent husband. Twenty-one percent report spousal emotional violence. Few ever-married women (3%) have ever initiated violence against their husband.

Although the prevalence spousal violence is lower among more educated women, 1 in 5 women who have at least 12 years of schooling have experienced physical or sexual spousal violence. The contextual and intergenerational aspects spousal violence are clear from the fact that women whose mothers were beaten by their fathers are twice as likely to be abusive marriages themselves. Women whose husbands consume alcohol are much more likely than women whose

Is alcohol use related to spousal physical or sexual violence?

Percentage of ever-married women experiencing violence

husbands do not consume alcohol to experience spousal violence, especially if the husband often gets drunk. However, 32 percent of even women whose husbands do not drink alcohol have experienced physical or sexual spousal violence.

More than one-quarter of women who have experienced spousal physical or sexual violence have suffered injuries as a result of the violence, and among women who have experienced both physical and sexual violence this proportion rises to 43 percent. The most common type of injury is cuts, bruises, or aches.

Help seeking

Only 13 percent of women who have ever experienced physical or sexual violence by anyone have sought help. Over four-fifths of women have neither sought help nor told anyone about the violence. Abused women who have sought help most often seek help from their own families. Only 3 percent of abused women who sought help for the violence sought help from the police.

Table 1 Results of the household and individual interviews

Number of households, number of interviews with women and men, and response rates, according to residence, Bihar, 2015-16

	Resid		
Result	Urban	Rural	Total

na = Not applicable

Nuclear households are households comprised of a married couple or a man or a woman living alone or with unmarried children (biological, adopted, or fostered) with or without unrelated individuals.

adopted, or fostered) with or without unrelated individuals.

2 Protected dug well, protected spring, rainwater, community RO plant

3 Surface water, unprotected dug well, unprotected spring, cart with small tank, tanker truck, bottled water

4 Total may add to more than 100.0 because households may use more than one method of purification

5 Appropriate water treatment methods include boiling, bleaching, filtering, and electronic purifying

6 Includes ventilated improved pit (VIP)/biogas latrine and twin pit/composting toilet

7 Facilities that would be considered improved if they were not shared by two or more households

8 Includes dry toilet

9 Houses made from mud, thatch, or other low-quality materials are called kachha houses, houses that use partly low-quality and partly high-quality materials are called pucca houses, and houses made with high quality materials throughout, including the floor, roof, and exterior walls, are called pucca houses.

10 Electricity, LPG/natural gas, or biogas

11 Includes coal/lignite, charcoal, wood, straw/shrubs/grass, agricultural crop waste, and dung cakes

12 Frequency of smoking by anyone inside the house

¹² Frequency of smoking by anyone inside the house

Table 5 Household possessions and land ownership

Percentage of urban, rural, and total households and *de jure* population possessing various household goods, means of transport, agricultural land, a house and farm animals and having a bank/post office account, health scheme/health insurance, a BPL card, and a long-lasting insecticide-treated (LLIN) mosquito net, Bihar, 2015-16

Note: Table includes only the contraceptive methods separately shown in the table and excludes users who obtained their method from friends/relatives or husband.

IUD = Intrauterine device; PPIUD = Postpartum intrauterine device

¹ Among women who were sterilized in the five years preceding the survey () Based on 25-49 unweighted cases

Table 27 Twelve-month contraceptive discontinuation rates

Among women age 15-49 who started an episode of contraceptive use within the five years preceding the survey, the percentage of episodes discontinued within 12 months, by reason for discontinuation and specific method, Bihar, 2015-16

				Reason for disco	ontinuation				_	
Method	Method failure	Desire to become pregnant	Other fertility related reason ¹	Side effects/health concerns	Wanted more effective method	Other method related reason ²	Other reason	Any reason ³	Switched to another method ⁴	Number of episodes of use ⁵
- I . II .	0.0		0.0	0.0	0.0	0.0	0.0	0.0	0.0	2.000
Female sterilization	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0	2,990
Pill	2.8	6.6	12.0	8.8	1.2	11.8	20.2	63.4	2.9	516
IUD or PPIUD	(5.2)	(2.9)	(2.3)	(9.0)	(1.2)	(6.5)	(6.3)	(33.3)	(2.8)	185
Condom/Nirodh	2.4	7.4	18.4	1.2	0.9	7.9	24.8	63.0	2.9	618
Other ⁶	4.1	3.7	12.3	3.1	1.0	8.2	13.9	46.2	5.0	420
All modern spacing methods ⁷	2.9	5.9	13.0	5.3	0.9	9.5	20.6	58.2	3.1	1,491
All spacing methods ⁸	3.0	6.0	12.9	4.6	1.3	8.8	19.0	55.5	3.6	1,835
All methods	1.2	2.2	4.9	1.7	0.5	3.3	7.2	21.0	1.4	4,832

Note: Figures are based on life table calculations using information on episodes of contraceptive use that began 3-62 months preceding the survey. All spacing methods includes the rhythm method and all methods includes male sterilization and the rhythm method, which are not shown separately. IUD = Intrauterine device; PPIUD = Postpartum intrauterine device

¹ Includes infrequent sex/husband away, difficult to get pregnant/menopausal, and marital dissolution/separation

² Includes lack of access/too far, costs too much, and inconvenient to use

³ Reasons for discontinuation are mutually exclusive and add to the total in this column

⁴ The episodes of use included in this column are a subset of the discontinued episodes included in the discontinuation rate. A woman is considered to have switched to another method if she used a different method in the month following discontinuation or if she gave "wanted a more effective method" as the reason for discontinuation and started another method within two months of discontinuation.

⁵ Number of episodes of use includes both episodes of use that were discontinued during the period of observation and episodes of use that were not discontinued during the period of observation

⁶ Includes injectables, female condom, diaphragm, foam/jelly, standard days method, LAM, withdrawal, rhythm, and other modern and traditional methods that are not shown separately

⁷ Includes other modern spacing methods that are not shown separately

⁸ Includes other spacing methods that are not shown separately

⁽⁾ Based on 25-49 unweighted cases

Table 28 Men's contraception-related perceptions and knowledge

Note: Numbers in this table correspond to the revised definition of unmet need described in Bradley et al., 2012, Revising Unmet Need for Family Planning, DHS Analytical Studies No. 25, ICF International, Calverton, Maryland, USA. Unmet need for family planning refers to fecund women who are not using contraception but who wish to postpone the next birth (spacing) or stop childbearing altogether (limiting). Specifically, women are considered to have unmet need for spacing if they are: at risk of becoming pregnant, not using contraception, and either do not want to become pregnant within the next two years, or are unsure if or when they want to become pregnant; pregnant with a mistimed pregnancy; postpartum amenorrhoeic for up to two years following a mistimed birth and not using contraception. Women are considered to have unmet need for limiting if they are: at risk of becoming pregnant, not using contraception, and want no (more) children; pregnant with an unwanted pregnancy; postpartum amenorrhoeic for up to two years following an unwanted birth and not using contraception. Women who are classified as infecund have no unmet need because they are not at risk of becoming pregnant. Unmet need for family planning is the sum of unmet need for spacing and unmet need for limiting. Total includes Christian women, who are not shown separately.

¹ Total demand is the sum of unmet need and met need

² Percentage of demand satisfied is met need divided by total demand

³ Modern methods include female sterilization, male sterilization, pill, IUD/PPIUD, injectables, male condom, female condom, standard days method, diaphragm, foam/jelly, lactational amenorrhoea method (LAM), and other modern methods

⁴ Not a Hindu, Muslim, or Christian

⁽⁾ Based on 25-49 unweighted cases

Note: Table is based on children who stayed in the household the night before the interview. Each of the indices is expressed in standard deviation units (SD) from the median of the WHO Child Growth Standards adopted in 2006. The indices in this table are NOT comparable to those based on the previously used 1977 NCHS/CDC/WHO Reference. Table is based on children with valid dates of birth (month and year) and valid measurement of both height and weight. Total includes Christian children and children belonging to "other" religions, who are not shown separately.

Recumbent length is measured for children under age 2, or in the few cases when the age of the child is unknown and the child is less than 85 cm; standing height is measured for all other children

Includes children who are below -3 standard deviations (SD) from the WHO Growth Standards population median

³ Excludes children whose mothers were not interviewed

Includes children whose mothers are deceased

⁴ first born twins (triplets, etc.) are counted as first birdhs because they do not have a previous birth interval ⁵ For women who are not interviewed, information is taken from the Household Questionnaire. Excludes children whose mothers are not listed in the household schedule

Excludes children whose mothers were not weighed and measured, children whose mothers were not interviewed, and children whose mothers are pregnant or gave birth within the preceding 2 months. Mother's nutritional status in terms of BMI (Body Mass Index) is presented in Table 70.

Table 61 Initial breastfeeding

Among last-born children who were born in the two years preceding the survey, the percentage who were ever breastfed, and the percentage who started breastfeeding within one hour and one day of birth, and among last-born children born in the two years preceding the survey who were ever breastfed, the percentage who received a prelacteal feed, by background characteristics, Bihar, 2015-16

Total	95.0	35.4	80.9	9,609	24.7	9,126

Note: Table is based on last-born children born in the past two years whether the children are living or dead at the time of interview. Total includes Christian children, children belonging to "other" religions, and children who were delivered in an "other" place of delivery, who are not shown separately.

TBA = Traditional birth attendant

¹ Includes children who started breastfeeding immediately after birth

 $^{^{\}rm 2}$ Includes children who started breastfeeding within one hour of birth

³ Children given something other than breast milk during the first three days of life

⁴ Doctor, nurse, midwife, auxiliary nurse midwife, lady health visitor, or other health personnel

⁽⁾ Based on 25-49 unweighted cases

Table 62 Breastfeeding status by age

Percent distribution of youngest children under two years living with the mother by breastfeeding status, percentage currently breastfeeding, and percentage of all children under two years using a bottle with a nipple, according to age in months, Bihar, 2015-16

0.4 9.0 0.4 10.4 2.0 14.0 1.7 6.2 1.3 4.8	2.0 4.3 15.0 26.4 8.4 6.5
4 0 7 8 9	2.0 2.0 1.7 1.3 1.0

Note: Breastfeeding status refers to a "24-hour" period (yesterday and last night). Children who are classified as breastfeeding and consuming plain water only consumed no liquid or solid supplements. The categories of not breastfeeding, exclusively breastfeeding and consuming plain water, non-milk liquids/juice, other milk, and complementary foods (solids and semi-solids) are hierarchical and mutually exclusive, and their percentages add to 100 percent. Thus children who receive breast milk and non-milk liquids and who do not receive other milk and who do not receive complementary foods are classified in the non-milk liquid category even though they may also get plain water. Any children who get complementary food are classified in the non-milk liquid category even though they may also get plain water. Any children who get complementary foods are classified in the non-milk liquid category even though they may also get plain water. Any children who get complementary foods are classified in the non-milk liquid category even though they may also get plain water. Any children who get complementary foods are classified in the non-milk liquid category even though they may also get plain water. Any children who get complementary foods are classified in the non-milk liquid category as long as they are breastfeeding as well.

Table 63 Median duration of breastfeeding and infant and young child feeding (IYCF) practices

Median duration (months) of breastfeeding among last-born children born in the last three years and percentage of youngest children age 6-23 months living with the mother who were fed with appropriate feeding practices based on the number of food groups and times they were fed during the day or night preceding the survey, by breastfeeding status and background characteristics, Bihar, 2015-16

Table 63 Median duration of breastfeeding and infant and young child feeding (IYCF) practices—Continued

Median duration (months) of breastfeeding among last-born children born in the last three years and percentage of youngest children age 6-23 months living with the mother who were fed with appropriate feeding practices based on the number of food groups and times they were fed during the day or night preceding the survey, by breastfeeding status and background characteristics, Bihar, 2015-16

Note: Total includes Christian children and children belonging to "other" religions, who are not shown separately.

na = Not applicable

Median durations are based on the distributions at the time of the survey of the proportion of births by months since birth. Includes children living and deceased at the time of the survey. It is assumed that children not currently living with the mother are not currently breastfeeding.

² Either exclusively breastfed or received breast milk and plain water and/or non-milk liquids only

³ Food groups are: a. infant formula, milk other than breast milk, cheese or yogurt or other milk products; b. foods made from grains or roots, including porridge or gruel, fortified baby food; c. vitamin A-rich fruits and vegetables; d. other fruits and vegetables; e. eggs; f. meat, poultry, fish, shellfish, or organ meats; g. beans, peas, lentis, or nuts; h. foods made with oil, fat, ghee, or butter

Receiving solid or semi-solid food at least twice a day for breastled infants 6-8 months and at least three times a day for breastled children 9-23 months

⁵ Includes two or more feedings of commercial infant formula, fresh, tinned and powdered animal milk, and yogurt

Non-breastfed children age 6-23 months are considered to be fed with a minimum standard of three Infant and Young Child Feeding Practices if they receive other milk or milk products at least twice a day, receive the minimum meal frequency, and receive solid or semi-solid foods from at least four food groups not induding the milk or milk products food group

Breastfeeding, or not breastfeeding and receiving two or more feedings of commercial infant formula, fresh, tinned, and powdered animal milk, and yogurt 3 Children are fed the minimum recommended number of times per day according to their age and breastfeeding status as described in footnotes 4 and 6

⁽⁾ Based on 25-49 unweighted cases

Based on fewer than 25 unweighted cases

Table 64 Child feeding practices and nutritional status of children by district

Among last-born children in the past 2 years, percentage breastfed within one hour of birth, percentage of children under age 6 months exclusively breastfed, and percentage of children under age five years dassified as malnourished according to three anthropometric indices of nutritional status: height-for-age, weight-for-height, and weight-for-age, by district, Bihar, 2015-16

	Among last-born children in the past 2 years		Percentage of children		Height-for-age ²	Weight-for-height Weight-for-age	Weight-for-age

Mother's anaemia status ⁴					
Not anaemic	29.8	25.2	1.1	56.2	7,529
Mildly anaemic	30.9	34.0	1.2	66.1	9,872
Moderately/severely anaemic	29.4	40.8	2.5	72.6	3,377
Total	30.2	31.8	1.4	63.5	21,408
NFHS-3 (2005-06)	29.6	46.8	1.6	78.0	2,047

Note: Table is based on children who stayed in the household the night before the interview. Prevalence of anaemia, based on haemoglobin levels, is adjusted for altitude using the CDC formula (Centers for Disease Control (CDC)). 1998. Recommendations to prevent and control iron deficiency in the United States. *Morbidity and Mortality Weekly Report* 47 (RR-3): 1-29). Haemoglobin levels shown in grams per decilitre (g/dl). Total includes Christian children and children belonging to "other" religions, who are not shown separately.

¹ Excludes children whose mothers were not interviewed

² For women who are not interviewed, information is taken from the Household Questionnaire. Excludes children whose mothers are not listed in the household schedule.

³ Includes children whose mothers are deceased

⁴ Mildly anaemic is classified as 10.0-11.9 g/dl for non-pregnant women and 10.0-10.9 g/dl for pregnant women. Moderately/severely anaemic is <10.0 g/dl. Adjusted for altitude and for smoking status. Excludes children whose mother's anaemia status is not known.

Table 66 Micronutrient intake among children

Percentage of youngest children age 9-23 months living with the mother who consumed vitamin A-rich and iron-rich foods in the day or night preceding the survey, percentage of children age 9-59 months who were given vitamin A supplements in the six months preceding the survey and percentage of children age 6-59 months who were given in the past seven days, who were given deworming medication in the six months preceding the survey, and who live in households using iodized salt, by background characteristics, Bihar, 2015-16, and total for NFHS-3

Note: Table is based on children/women who stayed in the household the night before the interview. Prevalence of anaemia, based on haemoglobin levels, is adjusted for altitude using the CDC formula (Centers for Disease Control (CDC)). 1998. Recommendations to prevent and control iron deficiency in the United States. *Morbidity and Mortality Weekly Report* 47 (RR-3): 1-29). Haemoglobin levels shown in grams per decilitre (g/dl). The Body Mass Index (BMI) is expressed as the ratio of weight in kilograms to the square of height in meters (kg/m²).

¹ For pregnant women, the value is <11.0 g/dl

² Excludes pregnant women and women with a birth in the preceding 2 months

Table 73 Knowledge and prevention of HIV/AIDS

Percentage of women and men age 15-49 who have heard of HIV or AIDS and who, in response to prompted questions, say that people can reduce the risk of getting HIV/AIDS by using a condom every time they have sexual intercourse, who know that the risk of HIV/AIDS can be reduced by limiting sex to one uninfected partner, who have a comprehensive knowledge about HIV/AIDS, and who know that HIV/AIDS can be transmitted from a mother to a baby, by background characteristics, Bihar, 2015-16

SBP = Systolic blood pressure; DBP = Diastolic blood pressure

A woman is dassified as having hypertension if she has SBP levels ≥ 140 mmHg or DBP ≥ 90 mmHg at the time of the survey, or she is currently taking antihypertension medication to control blood pressure. The term hypertension as used in this table is not meant to be a dinical diagnosis of the disease, but rather to provide an indication of the disease burden in the population at the

time of the survey.

SBP = Systolic blood pressure; DBP = Diastolic blood pressure

A man is classified as having hypertension if he has SBP levels ≥140 mmHg or DBP ≥90 mmHg at time of survey, or he is currently taking antihypertension medication to control blood pressure. The term hypertension as used in this table is not meant to be a clinical diagnosis of the disease, but rather to provide an indication of the disease burden in the population at the time of the survey.

violence and sought help	132	3	97	206	26	232

 $^{^{\}mbox{\scriptsize 1}}$ Women can report more than one source from which they sought help.

^{*} Percentage not shown; based on fewer than 25 unweighted cases

APPENDIX

ESTIMATES OF SAMPLING ERRORS

The estimates from a sample survey are affected by two types of errors: (1) non-sampling errors, and (2) sampling errors. Non-sampling errors are the results of mistakes made in implementing data collection and data processing, such as failure to locate and interview the correct household, misunderstanding of the questions on the part of either the interviewer or the respondent, and data entry errors. Although numerous efforts were made during the implementation of the fourth National Family Health Survey (NFHS-4) to minimize this type of error, non-sampling errors are impossible to avoid and difficult to evaluate statistically.

Sampling errors, on the other hand, can be evaluated statistically. The sample of respondents selected in NFHS-4 is only one of many samples that could have been selected from the same population, using the same design and expected sample size. Each of these samples would yield results that differ somewhat from the results of the actual sample selected. Sampling errors are a measure of the variability among all possible samples. Although the degree of variability is not known exactly, it can be estimated from the survey results.

A sampling error is usually measured in terms of the standard error for a particular statistic (mean, percentage, etc.), which is the square root of the variance. The standard error can be used to calculate confidence intervals within which the true value for the population can reasonably be assumed to fall. For example, for any given statistic calculated from a sample survey, the value of that statistic will fall within a range of plus or minus two times the standard error of that statistic in 95 percent of all possible samples of identical size and design.

If the sample of respondents had been selected as a simple random sample, it would have been possible to use straightforward formulas for calculating sampling errors. However, the NFHS-4 sample is the result of a multi-stage stratified design, and, consequently, it was necessary to use more complex formulae. The computer software used to calculate sampling errors for NFHS-4 is programmed in SAS. This procedure uses the Taylor linearization method for variance estimation for survey estimates that are means or proportions. The Jackknife repeated replication method is used for variance estimation of more complex statistics such as total fertility rates and child mortality rates.

The Taylor linearization method treats any proportion or mean as a ratio estimate, r = y/x, where y represents the total sample value for variable y, and x represents the total number of cases in the group or subgroup under consideration. The variance of r is computed using the formula given below, with the standard error being the square root of the variance:

$$SE^{2}(r) = var(r) = \frac{1 - f}{x^{2}} \sum_{h=1}^{H} \left[\frac{m_{h}}{m_{h} - 1} \left(\sum_{i=1}^{m_{h}} z_{hi}^{2} - \frac{z_{h}^{2}}{m_{h}} \right) \right]$$

in which

$$z_{hi} = y_{hi} - rx_{hi}$$
, and $z_h = y_h - rx_h$

where

h represents the stratum, which varies from 1 to H,

 n_h is the total number of clusters selected in the h^{th} stratum,

 y_{hi} is the sum of the weighted values of variable y in the i^{th} cluster in the h^{th} stratum,

 x_{hi} is the sum of the weighted number of cases in the i^{th} cluster in the h^{th} stratum, and

f is the overall sampling fraction, which is so small that it is ignored.

The Jackknife repeated replication method derives estimates of complex rates from each of several replications of the parent sample, and calculates standard errors for these estimates using simple formulae. Each replication considers all but one cluster in the calculation of the estimates. Pseudo-independent replications are thus created. In the NFHS-4 sample for Bihar, there were 1,677 clusters. Hence, 1,677 replications were created. The variance of a rate r is calculated as follows:

$$SE^{2}(r) = var(r) = \frac{1}{k(k-1)} \sum_{i=1}^{k} (r_{i} - r)^{2}$$

in which

$$r_i = kr - (k-1)r_{(i)}$$

where

r is the estimate computed from the full sample of 1,677 clusters,

 $r_{(i)}$ is the estimate computed from the reduced sample of 1,676 clusters

(ith cluster excluded), and

k is the total number of clusters.

In addition to the standard error, the design effect (DEFT) for each estimate is also computed, which is defined as the ratio between the standard error using the given sample design and the standard error that would result if a simple random sample had been used. A DEFT value of 1.0 indicates that the sample design is as efficient as a simple random sample, while a value greater than 1.0 indicates the increase in the sampling error due to the use of a more complex and less statistically efficient design. The relative standard error (SE/R) and confidence limits (R±2SE) for each estimate are also computed.

Sampling errors for NFHS-4 are calculated for selected variables considered to be of primary interest. The results are presented in this appendix for Bihar as a whole and for the urban and rural areas of the state. For each variable, the type of statistic (mean, proportion, rate, or ratio) and the base population are given in Table A.1. Table A.2 presents the value of the statistic (R), its standard error (SE), the number of unweighted (N) and weighted (WN) cases, the design effect (DEFT), the relative standard error (SE/R), and the 95 percent confidence limits (R±2SE); for each variable. The DEFT is considered undefined when the standard error for a simple random sample is zero (when the estimate is close to 0 or 1).

Variable	Estimate	Base population
valiable		
	HOUSEHO	
Using an improved source of drinking water	Proportion	Households
Using an improved sanitation facility	Proportion	Households
Using iodized salt Sex ratio (females per 1,000 males)	Proportion Ratio	Households De facto household population, all ages
